24 **Abstract**

25 In the present study, the butterhead lettuce cultivar was analyzed by ultrahigh performance liquid  
26 chromatography (UHPLC) coupled online to diode array detection (DAD), electrospray ionization  
27 (ESI) and quadrupole time-of-flight mass spectrometry (QToF/MS) in the positive and negative ion  
28 mode in order to characterize its polyphenolic profile for the first time. The instrument acquisition  
29 mode MS<sup>E</sup> was used to collect automatic and simultaneous information of exact mass at high and  
30 low collision energies of precursor ions as well as other ions produced as a result of their  
31 fragmentation. One hundred eleven phenolic compounds were identified in the acidified  
32 hydromethanolic extract of freeze-dried leaves of butterhead lettuce cultivar: 40 hydroxycinnamic  
33 acid derivatives, 21 hydroxybenzoic acid derivatives, 2 hydroxyphenylacetic acid derivatives, 18  
34 flavonols, 9 flavones, one flavanone, 7 coumarins, one hydrolysable tannin and 12 lignans. Forty  
35 seven of these compounds have been tentatively identified for the first time in lettuce.

39 Chemical compounds studied in this article:

40 5-Caffeoylquinic acid (PubChem CID: 12310830); caffeoylmalic acid (PubChem CID: 4484594);  
41 4-hydroxyphenylacetic acid (PubChem CID: 127); quercetin-3-*O*-galactoside (PubChem CID:  
42 90657624); quercetin-3-*O*-glucuronide (PubChem CID: 5274585); kaempferol-3-*O*-glucuronide  
43 (PubChem CID: 5318759); luteolin 7-glucoside (PubChem CID: 5280637); luteolin 7-rutinoside  
44 (PubChem CID: 44258082); esculetin-6-*O*-glucoside (PubChem CID: 5281417); syringaresinol  
45 (PubChem CID: 100067).

46

## 47 1. Introduction

48 Phenolic compounds are secondary plant metabolites ubiquitous in the plant kingdom  
49 involved in protection mechanisms against biotic and abiotic stresses, in the regulation of plant  
50 growth and development, and in the organoleptic quality of plant-based foods (Dai & Mumper,  
51 2010). Moreover, the intake of phenolic compounds through fruits and vegetables have been proved  
52 to provide beneficial effects attributed to their antioxidant capacity against oxidative stress, cancer  
53 and cardiovascular diseases, among others (Watson, Preedy, & Zibadi, 2014). Lettuce (*Lactuca*  
54 *sativa* L.) is one of the most popular leafy vegetables. In particular, the butterhead lettuce is one of  
55 the most commonly consumed variety worldwide (Agüero, Viacava, Ponce, & Roura, 2013);  
56 however, its polyphenolic profile has not been characterized yet to the authors' knowledge. The  
57 main classes of phenolic compounds found in different varieties of lettuce are phenolic acids and  
58 flavonols, followed by flavones and anthocyanins (only in red varieties) (Alarcón-Flores, Romero-  
59 González, Martínez Vidal, & Garrido Frenich, 2016; Marin, Ferreres, Barberá, & Gil, 2015; Pepe,  
60 Sommella, Manfra, De Nisco, Tenore, Scopa et al., 2015). Most analytical methods used to  
61 determine polyphenols in lettuce are based on high or ultrahigh performance liquid chromatography  
62 (HPLC or UHPLC) coupled to diode array detection (DAD) and/or mass spectrometry (MS and  
63 MS/MS) (Abu-Reidah, Contreras, Arráez-Román, Segura-Carretero, & Fernández-Gutiérrez, 2013;  
64 Alarcón-Flores et al., 2016; Altunkaya & Gökmen, 2009; Llorach, Martínez-Sánchez, Tomás-  
65 Barberán, Gil, & Ferreres, 2008; Pepe et al., 2015; Ribas-Agustí, Gratacós-Cubarsí, Sárraga,  
66 García-Regueiro, & Castellari, 2011). UHPLC achieves rapid analysis and better peak separation  
67 than HPLC, and coupled to ToF or QToF instruments provides a highly attractive analytical  
68 technique with very high resolution and accurate mass measurements of the precursor and fragment  
69 ions (Ramirez-Ambrosi, Abad-Garcia, Vilorio-Bernal, Garmon-Lobato, Berrueta, & Gallo, 2013).  
70 This technique has been already used to characterize 95 phenolic compounds in three lettuce  
71 cultivars (baby, romaine, and iceberg) (Abu-Reidah et al., 2013). Technological advances such as  
72 the so called MS<sup>E</sup> data acquisition mode has been successfully used for the structural elucidation of

73 phenolic compounds in complex plant extracts (Ramirez-Ambrosi et al., 2013). MS<sup>E</sup> acquisition  
74 method maximizes the QToF instrument duty cycle performing simultaneous collection of  
75 precursor ions as well as other ions produced as a result of their fragmentation in exact mass mode  
76 over a single experimental run. Since many compounds still remain unidentified in lettuce cultivars  
77 and the utilization of analytical edge technology can provide new structural information and allow  
78 the identification of unknown polyphenols, the present study exploits the use of UHPLC-DAD-ESI-  
79 QToF/MS<sup>E</sup> for the characterization of the polyphenolic profile of the butterhead lettuce cultivar,  
80 which is here reported for the first time to the authors' knowledge.

## 81 **2. Materials and Methods**

### 82 2.1. Reagents, solvents and standards

83 Water, methanol, acetonitrile, and formic acid (Fisher Scientific, Fair Lawn, NJ, USA) were  
84 of Optima® LC/MS grade; ascorbic acid (Panreac, Barcelona, Spain), analytical grade; and glacial  
85 acetic acid (Merck, Darmstadt, Germany), Suprapur® quality. Leucine Enkephalin acetate hydrate  
86 and sodium formate solution were provided by Sigma-Aldrich Chemie (Steinheim, Germany).  
87 Luteolin-7-*O*-glucoside, kaempferol-3-*O*-glucoside, quercetin-3-*O*-galactoside, quercetin-3-*O*-  
88 rhamnoside were purchased from Extrasynthèse (Genay, France); caffeoyltartaric acid and  
89 quercetin-3-*O*-glucoside, from Chromadex (Irvine, CA, USA); 5-*O*-caffeoylquinic acid, *p*-coumaric  
90 acid, 1,5-dicaffeoylquinic acid, 1,3-dicaffeoylquinic acid, and quercetin-3-*O*-rutinoside, from  
91 Sigma-Aldrich Chemie (Steinheim, Germany); and ferulic acid, caffeic acid, and 3,4-  
92 dihydroxybenzoic acid, from Fluka Chemie (Steinheim, Germany). Standard stock solutions of  
93 phenolic compounds were prepared in methanol; and a reference solution of these compounds  
94 (5 µg/mL), in methanol-water-acetic acid (30:65:5, v/v/v).

### 95 2.2. Plant material

96 Heads of butterhead lettuce (*Lactuca sativa* var. Lores) were obtained from a local producer  
97 in Sierra de los Padres (Mar del Plata, Argentina). Lettuce samples were frozen with liquid nitrogen

98 and freeze-dried, homogenized and crushed to obtain a homogeneous powder, which was stored at  
99 room temperature in dark in a desiccator until analysis.

### 100 2.3. Extraction of polyphenols in lettuce

101 Freeze-dried lettuce (0.1 g) was extracted with 5 mL of methanol-water-acetic acid (30:65:5,  
102 v/v/v) containing ascorbic acid (2 g/L) in an ultrasonic bath for 10 min. Then, the extract was  
103 centrifuged at 6000 rpm during 15 min at 4 °C, and the supernatant was filtered through a 0.45 µm  
104 PTFE filter (Waters, Milford, CA, USA) prior to injection into the UHPLC system.

### 105 2.4. UHPLC-DAD-ESI-QToF/MS<sup>E</sup>

106 Lettuce extract was analyzed using an ACQUITY UPLC<sup>TM</sup> system from Waters (Milford,  
107 MA, USA), equipped with a binary solvent delivery pump, an autosampler, a column compartment  
108 a PDA detector, and controlled by MassLynx v4.1 software. A reverse phase Acquity UPLC BEH  
109 C18 column (2.1 mm × 100 mm, 1.7 µm) and a Acquity UPLC BEH C18 VanGuard<sup>TM</sup> pre-column  
110 (1.7 µm) from Waters (Milford, USA) were used. Flow rate was 0.5 mL/min; injection volume, 5  
111 µL; column and autosampler temperatures, 40°C and 4 °C respectively. Mobile phases consisted of  
112 0.1% (v/v) acetic acid in water (A) and 0.1% (v/v) acetic acid in methanol (B). The elution  
113 conditions applied were: 0–8.5 min, linear gradient 0–13% B; 8.5–11 min, 13% B isocratic; 11–  
114 12.3 min, linear gradient 13–15% B; 12.3–13.8 min, linear gradient 15–19% B; 13.8–17.3 min,  
115 linear gradient 19–23% B; 17.3–19 min, 23% B isocratic; 19–24 min, linear gradient 23–30% B;  
116 24–26 min, 30% B isocratic; 26–27 min, linear gradient 30–100% B; 27–28 min, 100% B isocratic;  
117 and finally reconditioning of the column with 100% A isocratic. UV-visible spectra were recorded  
118 from 210 to 500 nm (20 Hz, 1.2 nm resolution). Hydroxybenzoic acids were monitored at 254 nm;  
119 flavanones at 280 nm; hydroxycinnamic acids and coumarins at 320 nm; flavonols and flavones at  
120 370 nm.

121 All MS data acquisitions were performed on a SYNAPT<sup>TM</sup> G2 HDMS with a quadrupole  
122 time of flight (QToF) configuration (Waters, Milford, MA, USA) equipped with an electrospray  
123 ionization (ESI) source operating in both positive and negative modes. The capillary voltage was set

124 to 0.7 kV (ESI+) or 0.5 kV (ESI-). Nitrogen was used as the desolvation and cone gas at flow rates  
125 of 900 L/h and 10 L/h, respectively. The source and desolvation temperatures were 120 °C and  
126 400 °C respectively. Leucine-enkephalin solution (2 ng/μL) in 0.1% (v/v) formic acid in  
127 acetonitrile-water (50:50, v/v) was used for the lock mass correction ( $m/z$  556.2771 and 278.1141,  
128 or  $m/z$  554.2615 and 236.1035, depending on the ionization mode, were monitored at scan time 0.2  
129 s, interval 10 s, scans to average 3, mass window  $\pm$  0.5 Da, cone voltage 30 V, at a flow rate  
130 10 μL/min). Data acquisition was recorded in the mass range 50–1200  $u$  in resolution mode  
131 (FWHM  $\approx$  20,000) with a scan time of 0.2 s and an interscan delay of the 0.024 s, and automatically  
132 corrected during acquisition based on the lock mass. Before analysis, the mass spectrometer was  
133 mass calibrated with the sodium formate solution. To perform MS<sup>E</sup> mode analysis, the cone voltage  
134 was set to 20 V (ESI+) or 30 V (ESI-) and the quadrupole operated in a wide band RF mode only.  
135 Two discrete and independent interleaved acquisition functions were automatically created. The  
136 first function, typically set at 6 eV in trap cell of the T-Wave, collects low energy or unfragmented  
137 data while the second function collects high energy or fragmented data typically using 6 eV in trap  
138 cell and a collision ramp 10–40 eV in transfer cell. In both cases, Argon gas was used for Collision  
139 Induced Dissociation (CID). Data were recorded in continuous mode. For instrument control, data  
140 acquisition and processing MassLynx™ software Version 4.1 (Waters MS Technology, Milford,  
141 USA) was used.

## 142 2.5. Identification of phenolic compounds

143 The identification of the phenolic compounds for which standards were available was carried  
144 out by the comparison of their retention times, their UV–vis spectra and MS<sup>E</sup> spectra recorded in  
145 positive and negative mode with those obtained by injecting standards in the same conditions. The  
146 identity of the rest of compounds was elucidated using the following analytical data: *i*) the UV–vis  
147 spectrum when it was available to assign the phenolic class (Abad-García, Berrueta, Garmón-  
148 Lobato, Gallo, & Vicente, 2009), since each class exhibits a characteristic UV–vis spectrum  
149 (Markham, 1982); *ii*) the low collision energy MS<sup>E</sup> spectrum in positive and negative ion mode to

150 determine the molecular weight; and since only the protonated/deprotonated molecules are able to  
151 form in the electrospray ionization source adducts, clusters and/or molecular complexes with  
152 mobile phase species (e.g. adducts with sodium  $[M+Na]^+$  at 22 *u* above the protonated molecule,  
153  $[2M+Na]^+$  of monoacyl hydroxycinnamic acids, the dehydrated protonated molecule ( $[M+H-$   
154  $H_2O]^+$ ) of phenolic acids and diacyl hydroxycinnamic acids in positive mode; and adducts with  
155  $HSO_4^-$  (97 *u*) and  $AcO^-$  (43 *u*) and the deprotonated dimer ion  $[2M-H]^-$  of monoacyl  
156 hydroxycinnamic acid in negative mode), their presence in the low collision energy spectra allows  
157 the unequivocal identification of the  $[M+H]^+$  or  $[M-H]^-$  ions; and *iii*) the high collision energy MS<sup>E</sup>  
158 spectrum provides the polyphenol fragmentation patterns, which afford structural information  
159 related to the type of carbohydrates, the sequence of the glycan part, interglycosidic linkages and  
160 the aglycone moiety, allowing to assign the protonated aglycone  $[Y_0]^+$  and/or the deprotonated  
161 aglycone  $[Y_0]^-$ . The identification of the aglycone was carried out based on the observation of <sup>*ij*</sup>A<sup>+</sup>  
162 and <sup>*ij*</sup>B<sup>+</sup> ions (Ma, Li, Van den Heuvel, & Claeys, 1997). Furthermore, the chromatographic elution  
163 order aided in some structural assignments, as well as bibliographic references. IUPAC  
164 nomenclature and recommended numbering system (Lozac'h, 1975) were used for chlorogenic  
165 acids and flavonoids; and common names were used for other phenolic acid derivatives, coumarins,  
166 hydrolysable tannins and lignan derivatives. Structures of each family of compounds studied are  
167 presented in Fig. 1.

### 168 **3. Results and Discussion**

169 A total of 111 phenolic compounds were tentatively identified in the butterhead lettuce  
170 cultivar by UHPLC-DAD-ESI-QToF/MS<sup>E</sup>. The UV-visible and MS spectral data are summarized in  
171 Table 1. DAD and MS chromatograms are shown in Figs. 1S-5S (supplementary material). The  
172 high and low energy function MS spectra of compounds from the different phenolic families  
173 detected in this cultivar are displayed in Figs. 2 and 3, and in Figs. 6S-9S (supplementary material).

#### 174 **3.1. Phenolic acid derivatives**

175 For the identification of phenolic acid derivatives, mainly negative ion mode mass spectra  
176 were taken into account, although the positive ion mode was used for verification. In the high  
177 collision energy MS spectra, losses of H<sub>2</sub>O, CO<sub>2</sub> and CO were regularly observed, which have also  
178 been described by other authors using IT, QqQ, and QToF (Gómez-Romero, M., Segura-Carretero,  
179 & Fernandez-Gutierrez, 2010; Ramirez-Ambrosi et al., 2013).

### 180 **3.1.1. Hydroxycinnamic derivatives**

#### 181 **3.1.1.1. Caffeoylquinic acids**

182 Three major chromatographic peaks (**1**, **3**, **6**), presenting the same UV spectra as the standard  
183 *trans*-5-caffeoylquinic acid (*trans*-5-CQA), were detected in the chromatograms extracted from the  
184 Total Ion Current (TIC) MS scan chromatogram in negative and positive modes at *m/z* 353 and 355  
185 respectively, which were due to three caffeoylquinic acid (CQA) isomers (Fig. 2S in the  
186 supplementary material). Compound **3** (R<sub>t</sub>= 7.32 min, λ<sub>max</sub>= 300, 324 nm) was identified  
187 unambiguously as *trans*-5-caffeoylquinic acid by comparison with its standard: the deprotonated  
188 molecule [M-H]<sup>-</sup> at *m/z* 353 yielded fragment ions at *m/z* 191, 173 and 135; and the protonated  
189 molecule [M+H]<sup>+</sup>, at *m/z* 163 and 145. Moreover, its sodium adducts, [M+Na]<sup>+</sup> and [2M+Na]<sup>+</sup> at  
190 *m/z* 377 and 731 respectively, were also observed (Fig. 6S in the supplementary material).  
191 Compounds **1** (R<sub>t</sub>= 4.74 min, λ<sub>max</sub>= 301, 323 nm) and **6** (R<sub>t</sub>= 10.23 min, λ<sub>max</sub>= 301, 316 nm) had  
192 the same fragmentation pattern as 5-CQA, and their *m/z* values for [M+H]<sup>+</sup> and [M-H]<sup>-</sup> were  
193 confirmed with the sodium adduct at *m/z* 377 in positive ionization mode, and the [2M-H]<sup>-</sup> ion at  
194 *m/z* 707 in negative mode. All three peaks (**1**, **3**, **6**) yielded the same base peak at *m/z* 191 due to the  
195 deprotonated quinic moiety in the negative high energy function. None of the peaks yielded an  
196 intense fragment ion at *m/z* 173 ([quinic acid-H-H<sub>2</sub>O]<sup>-</sup>). This dehydrated ion of quinic acid is  
197 characteristically formed in the negative ion mode when the cinnamoyl group is bonded to the  
198 quinic moiety at position 4, as already noted by other authors using other QqQ/MS (Alonso-Salces,  
199 Guillou, & Berrueta, 2009) or IT/MS (Clifford, Johnston, Knight, & Kuhnert, 2003). Peak **1** also  
200 gave intense ions from the caffeoyl moiety ([caffeic acid-H-CO<sub>2</sub>]<sup>-</sup>) at *m/z* 135 (71% relative

201 abundance (RA)) and ([caffeic acid-H]<sup>-</sup>) at *m/z* 179 (32% RA), characteristic intense ions of the  
202 fragmentation pattern of 3-CQA by QqQ/MS (Alonso-Salces et al., 2009). The relative  
203 hydrophobicity of cinnamoyl derivatives depends on the position, the number and the identity of the  
204 cinnamoyl residues. In general, those chlorogenic acids (CGAs) with a greater number of free  
205 equatorial hydroxyl groups in the quinic acid are more hydrophilic than those with a greater number  
206 of free axial hydroxyl groups (Clifford, Knight, & Kuhnert, 2005). Taking into account the fact that  
207 the hydroxyl groups in the quinic acid are axial in position 1 and 3, and equatorial in positions 4 and  
208 5 (Clifford, Knight, Surucu, & Kuhnert, 2006), the elution order observed for monoacyl-CGAs on  
209 C18 reversed-phase LC is 3-CGA, 5-CGA and 4-CGA. This empirical rule was observed by several  
210 authors (Abu-Reidah et al., 2013; Alonso-Salces et al., 2009; Clifford et al., 2003). So, isomers  
211 substituted in position 3 were the most hydrophilic; and in position 4 the most hydrophobic,  
212 although in some packings 4-CQA precedes 5-CQA. On the other hand, the ease of removal of the  
213 caffeoyl residue during fragmentation is  $1 \approx 5 > 3 > 4$  (Clifford et al., 2005). In the negative low  
214 energy function, the base peaks were [M-H]<sup>-</sup> at *m/z* 353 for peak **1**, and [quinic acid-H]<sup>-</sup> at *m/z* 191  
215 for peaks **3** and **6**, revealing that the caffeoyl moiety in peak **1** was bonded to the quinic structure in  
216 a stronger position. So, peak **1** was tentatively assigned to a 3-CQA isomer.

217 Besides the three major peaks (**1**, **3**, **6**), other four caffeoylquinic acid isomers (**2**, *Rt*= 6.65  
218 min; **4**, *Rt*= 8.12 min; **5**, *Rt*= 8.36 min; **7**, *Rt*= 15.06 min) were detected in the chromatograms  
219 extracted at *m/z* 353 (ESI<sup>-</sup>) and 355 (ESI<sup>+</sup>), presenting the same fragmentation pattern in the  
220 positive mode as the former isomers. Chlorogenic acid isomers 1-CQA, 3-CQA (neochlorogenic  
221 acid), *cis*-3-CQA, 4-CQA (cryptochlorogenic acid), *cis*-4-CQA and *cis*-5-CQA have been  
222 previously found in different *Asteraceae* species (Clifford, Wu, Kirkpatrick, & Kuhnert, 2007;  
223 Jaiswal, Kiprotich, & Kuhnert, 2011). In the negative low energy function, compounds **2**, **4** and **7**  
224 yielded the deprotonated molecule [M-H]<sup>-</sup>, whereas all four peaks presented the same base peak at  
225 *m/z* 191 due to the deprotonated quinic moiety in the negative high energy function. Furthermore,  
226 peak **4** yielded ions at *m/z* 135 (21% RA) and at *m/z* 179 (12% RA); and peak **5**, at *m/z* 173 (13%

227 RA), whereas for all other isomers, this ion was less than 4% RA. Peak **5**, presenting the most  
228 intense  $m/z$  173 and eluting later than 5-CQA (**3**), was ascribed to a 4-CQA isomer.

229 It is widely accepted that *trans* isomers are the substrates and products of the main  
230 phenylpropanoid biosynthetic pathway, being the predominant species detected in plant tissues.  
231 However it is also known that conversion to the *cis* form occurs readily, especially after exposure to  
232 UV light, and therefore *cis* isomers might reasonably be expected in plant extracts (Clifford,  
233 Kirkpatrick, Kuhnert, Roozendaal, & Salgado, 2008). Indeed, *cis*-3-CQA, *cis*-4-CQA and *cis*-5-  
234 CQA have been previously found in different *Asteraceae* species (Clifford et al., 2005; Clifford et  
235 al., 2007; Jaiswal et al., 2011). *Cis* isomers fragment identically to the more common *trans* isomers,  
236 however *cis* and *trans* isomers are easily resolved by chromatography. *Cis*-5-acyl and *cis*-1-acyl  
237 CGAs are more hydrophobic, thus elute later than their *trans* isomers, whereas the opposite happens  
238 with *cis*-3-acyl and *cis*-4-acyl CGAs on endcapped C18 and phenylhexyl packings (Clifford et al.,  
239 2008). These observations helped to tentatively identify some compounds. Thus, peak **6** was  
240 attributed to *cis*-5-CQA, taking into account the elution order of *cis* and *trans* isomers; the fact that  
241 absorption maximum for *cis*-CGA occurs at shorter wavelength than for their *trans* form  
242 (Dawidowicz & Typek, 2011); and that it is a major peak as its *trans* isomer. Peaks **1** and **4**, which  
243 showed similar fragmentation patterns, were designated to the *trans* and *cis* isomers of 3-CQA  
244 respectively.

245 Peak **2** showed a similar fragmentation pattern to peaks **3** and **6**. Indeed, 1-CQA and 5-CQA  
246 are not possible to be reliably distinguished by their fragmentation (Clifford et al., 2005).  
247 Fortunately, *trans*-5-CQA is readily available from commercial sources, and 1-CQA can be easily  
248 resolved in the chromatographic elution from this, so, in practice, discrimination is straightforward.  
249 Peak **2** eluted earlier than *trans*-5-CQA (**3**) and was assigned to a 1-acyl isomer. The remaining  
250 peak (**7**) eluted the latest of all CQA, therefore it was ascribed to the other 4-CQA isomer.

251 Taking into account all the above considerations, the chromatographic peaks were tentatively  
252 identified as: **1**, *trans*-3-CQA; **2**, *trans*-1-CQA; **3**, *trans*-5-CQA; **4**, *cis*-3-CQA; **5**, *trans*-4-CQA; **6**,

253 *cis*-5-CQA; and **7**, *cis*-4-CQA. Only three CQA isomers had been reported previously in green  
254 lettuce, i.e. 5-CQA, 3-CQA and an unidentified CQA isomer (Abu-Reidah et al., 2013; Jeong, Kim,  
255 Lee, Kim, Kang, Jin et al., 2015). *trans*-5-CQA (**3**) was the major phenolic compound in butterhead  
256 lettuce, as occurs in other green lettuce cultivars (Llorach et al., 2008; Ribas-Agustí et al., 2011;  
257 Sobolev, Brosio, Gianferri, & Segre, 2005). The following major CQAs were *cis*-5-CQA and *trans*-  
258 3-CQA (20% and 8% of the total intensity of *trans*-5-CQA).

### 259 **3.1.1.2. *p*-Coumaroylquinic acids**

260 Compounds **8** (Rt= 9.82 min,  $\lambda_{\max}$ = 312 nm) and **9** (Rt= 13.74 min,  $\lambda_{\max}$ = 308 nm) were  
261 identified as *p*-coumaroylquinic acid isomers on the basis of mass spectral data and UV spectra,  
262 which followed the pattern of the *p*-coumaric acid standard. In both low and high energy positive  
263 ion mode, the sodium adduct  $[M+Na]^+$  at  $m/z$  361 was the base peak for both compounds, and the  
264 ion at  $m/z$  147 ( $[p\text{-coumaroyl}+H]^+$ ) was the secondary most intense ion. In the negative low energy  
265 function, the base peaks were  $[M-H]^-$  at  $m/z$  337 for peak **8** (Fig. 3S in the supplementary material),  
266 and  $[quinic\ acid-H]^-$  at  $m/z$  191 for peak **9**, revealing that the *p*-coumaroyl moiety in peak **8** was  
267 bonded to the quinic structure in a stronger position. Moreover, peak **8** yielded in the high energy  
268 function an intense ion at  $m/z$  119 due to its decarboxylation product  $[p\text{-coumaric\ acid-H-CO}_2]^-$ ,  
269 which is characteristic of the fragmentation pattern of 3-*p*-coumaroylquinic acid, thus this isomer  
270 was tentatively assigned to peak **8**, for the first time in lettuce cultivars. The base peak of compound  
271 **9** at  $m/z$  191 due to the deprotonated quinic moiety is characteristic of 5-*p*-coumaroylquinic acid  
272 (Clifford et al., 2003). Similarly to CQA isomers, the elution order of both isomers on endcapped  
273 C18 packings agrees with these tentatively assignments. 5-*p*-coumaroylquinic acid and an  
274 unidentified isomer have been previously reported in bibliography in green lettuce cultivars (Abu-  
275 Reidah et al., 2013; Ribas-Agustí et al., 2011).

### 276 **3.1.1.3. Caffeoyltartaric acid**

277 A caffeoyltartaric acid (peak **10**: Rt= 9.06 min,  $\lambda_{\max}$ = 301, 323 nm) was detected in the  
278 extracted MS chromatogram set at 311 in the negative ion mode (Fig. 3S in the supplementary

279 material), presenting the corresponding fragmentation pattern: The dehydrated protonated molecule  
280 at  $m/z$  293 was the base peak in low energy function; and intense fragments of the deprotonated  
281 tartaric ( $m/z$  149) and caffeic ( $m/z$  179) acids and the losses of water ( $m/z$  293) and  $\text{CO}_2$  ( $m/z$  135;  
282 base peak) were observed in the high energy function. Two isomers of caffeoyltartaric acid have  
283 been already reported in lettuce in literature (Abu-Reidah et al., 2013; Jeong et al., 2015; Lin,  
284 Harnly, Zhang, Fan, & Chen, 2012; Ribas-Agustí et al., 2011; Santos, Oliveira, Ibáñez, & Herrero,  
285 2014).

#### 286 **3.1.1.4. *p*-Coumaroyltartaric acid**

287 Peak **11** ( $R_t$ = 15.63 min,  $\lambda_{\text{max}}$ = 310 nm), detected in the extracted MS chromatogram set at  
288  $m/z$  295 in the negative ion mode, yielded the base peak at  $m/z$  163 due to the deprotonated *p*-  
289 coumaric acid, and two fragments at  $m/z$  149 (50% RA) and  $m/z$  119 (60% RA) due to the  
290 deprotonated tartaric acid and the decarboxylation of *p*-coumaric acid in the low energy function.  
291 Thus, compound **11** was tentatively identified as *p*-coumaroyltartaric acid, which has been  
292 previously found in green lettuce cultivars (Abu-Reidah et al., 2013; Ribas-Agustí et al., 2011).

#### 293 **3.1.1.5. Caffeoylmalic acid**

294 Caffeoylmalic acid (CMA) (peak **12**:  $R_t$ = 9.05 min,  $\lambda_{\text{max}}$ = 301, 323 nm) was detected when  
295 the  $m/z$  value for the extracted MS chromatogram was set at 295 (negative ion mode) or 297  
296 (positive ion mode). Besides the UV spectra of peak **12** followed the pattern of caffeic acid  
297 standard. In the negative ion mode, the high energy function provided ions corresponding to malic  
298 acid: the base peak at  $m/z$  133 was due to the deprotonated malic moiety; and fragment ions, to the  
299 losses of water and CO at  $m/z$  115 and 105 respectively.  $\text{MS}^E$  experiments in the positive ion mode  
300 showed that CMA behaved as described above for CQA, yielding the same ions from the caffeoyl  
301 moiety, as well as the sodium adduct. CMA has been described before in different lettuce cultivars  
302 (Abu-Reidah et al., 2013; Lin et al., 2012; Ribas-Agustí et al., 2011; Santos et al., 2014).

#### 303 **3.1.1.6. Dicaffeoylquinic acids and caffeoylquinic acid glycosides**

304 Both dicaffeoylquinic acids (diCQA) and caffeoylquinic acid-hexosides present an average  
305 molecular mass of 516 *u*, and produce isobaric deprotonated or protonated molecules at *m/z* 515 and  
306 517 in the negative and positive ion modes respectively. Five peaks were detected in the extracted  
307 MS chromatograms at these *m/z* values: peak **13** (Rt= 5.86), peak **14** (Rt= 7.56), peak **15** (Rt=  
308 20.20,  $\lambda_{\text{max}}$ = 321 nm), peak **16** (Rt= 20.63,  $\lambda_{\text{max}}$ = 326 nm) and peak **17** (Rt= 24.17,  $\lambda_{\text{max}}$ = 331  
309 nm). Based on their accurate masses and fragmentation patterns, these peaks were distinguished as  
310 either di-caffeoylquinic acids (**15**, **16** and **17**) with monoisotopic  $[\text{M}-\text{H}]^-$  at *m/z* 515.1190  
311 ( $\text{C}_{25}\text{H}_{23}\text{O}_{12}$ ) and monoisotopic  $[\text{M}+\text{H}]^+$  at *m/z* 517.1346 ( $\text{C}_{25}\text{H}_{25}\text{O}_{12}$ ), and caffeoylquinic acid-  
312 hexosides (**13** and **14**) with monoisotopic  $[\text{M}-\text{H}]^-$  at *m/z* 515.1401 ( $\text{C}_{22}\text{H}_{27}\text{O}_{14}$ ) and monoisotopic  
313  $[\text{M}+\text{H}]^+$  at *m/z* 517.1548 ( $\text{C}_{22}\text{H}_{29}\text{O}_{14}$ ), in the negative and positive ion modes respectively.

314 It is worth to note that the first fragments of the diCQA were due to the loss of one of the  
315 caffeoyl moieties, leading to the precursor ion of a CQA (Fig. 2S in the supplementary material);  
316 therefore, subsequent fragmentation of these ions yielded the same fragments as the corresponding  
317 CQA. In the positive low energy function, the sodium adducts at *m/z* 539 and the dehydrated  
318 protonated molecule at *m/z* 499 were detected with different % RA: peak **15**,  $[\text{M}+\text{H}-\text{H}_2\text{O}]^+$  base  
319 peak and  $[\text{M}+\text{Na}]^+$  80% RA; peak **16**,  $[\text{M}+\text{Na}]^+$  base peak and  $[\text{M}+\text{H}-\text{H}_2\text{O}]^+$  20% RA; and peak **17**,  
320  $[\text{M}+\text{Na}]^+$  base peak and  $[\text{M}+\text{H}-\text{H}_2\text{O}]^+$  90% RA. The positive high energy function gave a base peak  
321 at *m/z* 163 ( $[\text{caffeic acid}+\text{H}-\text{H}_2\text{O}]^+$ ) for the three peaks, but  $[\text{M}+\text{Na}]^+$  presented 50% RA for peak  
322 **15**, 35% RA for peak **16**, and 70% RA for peak **17**. The % RA differences between these ions are  
323 related to the difficulty of removing the acylating residue at the different positions. In accordance  
324 with this, the negative low energy function MS spectra disclosed that peak **17** yielded only the  
325 deprotonated molecule (*m/z* 515) as the base peak; peak **15**, the base peak  $[\text{M}-\text{H}]^-$  and the fragment  
326  $[\text{CQA}-\text{H}]^-$  ion at *m/z* 353 with 65% RA; and peak **16**, the base peak  $[\text{CQA}-\text{H}]^-$  at *m/z* 353 and  
327  $[\text{M}-\text{H}]^-$  with 40% RA. Hence, these observations suggest that peak **17** contains a caffeoyl moiety at  
328 the positions more difficult to be removed ( $4 > 3 > 5 \approx 1$ ) (Clifford et al., 2003; Clifford et al.,  
329 2005) than the other peaks, followed by peak **15**. Indeed, the presence of the dehydrated quinic

330 residue ion [quinic acid-H-H<sub>2</sub>O]<sup>-</sup> at *m/z* 173 as the base peak in the high negative energy spectra of  
331 peak **17** revealed that one of the caffeoyl moieties was bonded to quinic acid at position 4. Then it  
332 remained to be determined if the other caffeoyl moiety was substituted at position 1, 3 and 5.  
333 Finally, taking also into account the elution order of diCQA isomers (retention time on endcapped  
334 C18 packings: 1,3-diCQA <<< 1,4-diCQA << 3,4-diCQA < 1,5-diCQA < 3,5-diCQA << 4,5-  
335 diCQA) reported in bibliography (Alonso-Salces et al., 2009; Clifford et al., 2005), compound **17**  
336 was assigned to 4,5-diCQA. In the high negative energy function, base peaks of compounds **15** and  
337 **16** were [quinic acid-H]<sup>-</sup> at *m/z* 191, whereas the characteristic fragment at *m/z* 173 corresponding  
338 to the dehydrated quinic residue ion was not detected. Therefore, caffeoyl moieties were substituted  
339 at position 1, 3 and 5. Compound **15** was identified unambiguously as 1,5-diCQA by comparison  
340 with its standard. Thus, regarding its retention time and the ease of removal of the caffeoyl residue,  
341 compound **16** was assigned to 3,5-diCQA. Isomers 3,5-diCQA (isochlorogenic acid A), *cis*-3,5-  
342 diCQA, and 4,5-diCQA (isochlorogenic acid B) have previously been reported in *L. sativa* (Abu-  
343 Reidah et al., 2013; Lin et al., 2012; Llorach et al., 2008; Ribas-Agustí et al., 2011). Among these,  
344 isochlorogenic acid A was reported to be the most abundant in lettuce, as found in the present study,  
345 which supported the assignment of compound **16** (Jeong et al., 2015; Mai & Glomb, 2013; Romani,  
346 Pinelli, Galardi, Sani, Cimato, & Heimler, 2002). 1-acyl CGA have been found in some Asteraceae  
347 (Clifford et al., 2005), however the isomer 1,5-diCQA is reported in lettuce here for the first time.

348 Caffeoylquinic acid-hexosides (**13** and **14**) base peaks were their sodium adducts in the  
349 positive ion mode and the deprotonated molecule in the negative ion mode, which confirmed their  
350 identities. The presence of the fragment ion at *m/z* 353 due to the deprotonated CQA, and the base  
351 peak at *m/z* 191 due to the deprotonated quinic acid in the negative high energy function of peak **13**  
352 also support the assignment. Peak **14** was at trace levels, not being possible to register its  
353 fragmentation pattern. To the authors' knowledge, caffeoylquinic acid-hexosides have not been  
354 reported in lettuce before.

#### 355 **3.1.1.7. *p*-Coumaroylcaffeoylquinic acids**

356 Two chromatographic peaks showed protonated and deprotonated molecules that  
357 corresponded to *p*-coumaroylcaffeoylquinic acids, at *m/z* 501 in the positive ion mode and at *m/z*  
358 499 in the negative mode: peak **18** (*R*<sub>t</sub>= 23.58 min, λ<sub>max</sub>= 312 nm) and peak **19** (*R*<sub>t</sub>= 23.95 min,  
359 λ<sub>max</sub>= 316 nm). In the positive high energy function, the base peaks yielded by both isomers were  
360 the fragment ion at *m/z* 147 due to [*p*-coumaroyl+H]<sup>+</sup>, disclosing that the *p*-coumaroyl moiety was  
361 attached to the quinic acid in a weaker position than the caffeoyl one. This was also supported by  
362 the fragmentation pattern observed for both peaks in the negative ion mode, which yielded the  
363 deprotonated molecules, and fragments at *m/z* 353 due to the loss of the *p*-coumaroyl moiety (85-  
364 95% RA) (Fig. 2S in the supplementary material) and at *m/z* 337 due to the loss of the caffeoyl  
365 moiety (40-50% RA) (Fig. 3S in the supplementary material) in the low energy function, indicating  
366 that the former loss was favored. This fragmentation pattern was reported for 3-*p*-coumaroyl-4-  
367 caffeoylquinic acid (3-*p*Co-4-CQA) and 4-caffeoyl-5-*p*-coumaroylquinic acid (4-C-5-*p*CoQA)  
368 (Clifford, Marks, Knight, & Kuhnert, 2006). The deprotonated quinic acid ion at *m/z* 191 was the  
369 base peak in the high energy function; this fragment is a characteristic base peak of 5-CQA, 3-CQA  
370 and 5-*p*CoQA, and is yielded by 4-CQA (Clifford et al., 2003). Thus, taking also into account that  
371 the elution order on endcapped C18 packing is 3,4-isomers, 3,5-isomers and 4,5-isomers (Clifford,  
372 Marks, et al., 2006), compounds **18** and **19** were tentatively assigned to 3-*p*Co-4-CQA and 4-C-5-  
373 *p*CoQA respectively, for the first time in lettuce cultivars. *p*-Coumaroylcaffeoylquinic acids have  
374 been previously reported in lettuce (Abu-Reidah et al., 2013; Jaiswal et al., 2011).

#### 375 **3.1.1.8. DicaFFEoyltartaric acids**

376 Two peaks (**20**, **21**), presenting the same UV spectra as caffeic acid standard, were detected  
377 in the chromatograms extracted from the TIC MS scan chromatogram in positive and negative  
378 modes at *m/z* 475 and 473, respectively, which were due to two dicaFFEoyltartaric acid isomers  
379 (diCTA). Compound **20** (*R*<sub>t</sub>= 10.53 min, λ<sub>max</sub>= 301, 324 nm) and compound **21** (*R*<sub>t</sub>= 12.54 min,  
380 λ<sub>max</sub>= 301, 323 nm) presented the same fragmentation pattern, and their identity was confirmed  
381 with the sodium adduct at *m/z* 497 in positive ionization mode and the [2M-H]<sup>-</sup> ion at *m/z* 947 in

382 negative mode for peak **20**, and the protonated and deprotonated molecules for peak **21**. In the  
383 negative ion mode, both peaks (**20**, **21**) yielded the same base peak at  $m/z$  293 due to the loss of  
384 water of the deprotonated caffeoyltartaric acid, and  $[CTA-H]^-$  at  $m/z$  311 due to the loss of one of  
385 the caffeoyl moieties (Fig. 3S in the supplementary material), as well as ions from the tartaric  
386 moiety,  $[tartaric\ acid-H]^-$  at  $m/z$  149 and  $[tartaric\ acid-H-CO_2]^-$  at  $m/z$  105; and ions from the  
387 caffeoyl moiety,  $[caffeic\ acid-H]^-$  at  $m/z$  179 and  $[caffeic\ acid-H-CO_2]^-$  at  $m/z$  135. Compound **20**  
388 was tentatively identified as di-*O*-caffeoyltartaric (chicoric acid), and compound **21** as meso-di-*O*-  
389 caffeoyltartaric acid, since they were detected in lettuce elsewhere; the former being reported as the  
390 most abundant as we observed (Abu-Reidah et al., 2013; Jeong et al., 2015; Lin et al., 2012; Mai &  
391 Glomb, 2013; Pepe et al., 2015; Ribas-Agustí et al., 2011; Romani et al., 2002; Santos et al., 2014).

#### 392 **3.1.1.9. Other hydroxycinnamic acid derivatives**

393 Several cinnamoyl glycosides were found in the lettuce extracts, such as caffeoyl-hexosides,  
394 *p*-coumaroyl-hexosides, sinapoyl-hexosides and dihydrocaffeic acid-hexosides, whose  
395 fragmentation patterns were characterized by the aglycone product ion resulted from the loss of a  
396 hexose residue (Abu-Reidah et al., 2013; Gómez-Romero, María, Zurek, Schneider, Baessmann,  
397 Segura-Carretero, & Fernández-Gutiérrez, 2011).

398 Eight peaks (**22**,  $R_t= 5.39$  min; **23**,  $R_t= 5.64$  min; **24**,  $R_t= 6.08$  min,  $\lambda_{max}= 301, 325$  nm; **25**,  
399  $R_t= 7.69$  min; **26**,  $R_t= 8.44$  min; **27**,  $R_t= 9.01$  min; **28**  $R_t= 9.52$  min; and **29**  $R_t= 9.64$  min) were  
400 observed in the chromatogram extracted at  $m/z$  343 and 341 in positive and negative ion modes  
401 respectively (Fig. 2S in the supplementary material). All of them (**22-29**) produced  $m/z$  179 and 135  
402 in negative ion mode, and  $m/z$  163, 145, 135, 117 and 89 in positive ion mode, consistent with the  
403 presence of a caffeic acid residue. Thus, these compounds were tentatively assigned as isomeric  
404 caffeic acid-hexosides, in agreement with Clifford et al. (2007) (Clifford et al., 2007). Moreover,  
405 the identity of peaks **22-26** and **28** were confirmed by the presence of their sodium adducts in the  
406 positive low energy function. As well, peak **30** ( $R_t= 8.01$  min,  $\lambda_{max}= 301, 325$  nm) showed the  
407 same fragmentation pattern as caffeic acid, yielding also a monoisotopic protonated molecule at

408  $m/z$  359.0802 ( $C_{18}H_{15}O_8$ ) in the positive ion mode, and a monoisotopic deprotonated molecule at  
409  $m/z$  357.0633 ( $C_{18}H_{13}O_8$ ) in the negative ion mode. Thus, it was tentatively assigned as a caffeoyl  
410 derivative, however the nature of the non-phenolic residue (196.0387  $u$ ) was not able to be  
411 disclosed. Such caffeoyl derivative has not previously been reported in lettuce so far we are aware.

412 Similarly, four isomers of synapic acid-hexosides (**31**,  $R_t= 6.03$  min,  $\lambda_{max}= 301, 326$  nm;  
413 **32**,  $R_t= 9.70$  min; **33**,  $R_t= 10.36$  min; **34**,  $R_t= 13.13$  min) were tentatively identified in the extracted  
414 traces at  $m/z$  387 and 385 in the positive and the negative ion modes respectively (Fig. 2S in the  
415 supplementary material). Ions corresponding to the deprotonated aglycone at  $m/z$  223, and the  
416 subsequent decarboxylations and losses of methyl residues at  $m/z$  208, 179, 164, and 149 from the  
417 synapoyl moiety were detected in the negative ion mode. In addition, the positive ion mode yielded  
418 the sodium adduct at  $m/z$  409 and ions due to the loss of the hexose residue at  $m/z$  225, and  
419 subsequent losses of  $H_2O$  at  $m/z$  207,  $CH_3OH$  at  $m/z$  192, and  $CO$  at  $m/z$  129. One isomer of synapic  
420 acid-hexoside has been previously reported in green lettuce cultivars (Abu-Reidah et al., 2013).

421 Following this fragmentation patterns, a *p*-coumaric acid-hexoside (**35**,  $R_t= 8.32$  min) and  
422 two dihydrocaffeic acid-hexosides (**36**,  $R_t= 3.70$  min; **37**,  $R_t= 3.83$  min) were also characterized.  
423 All of them yielded the product ion due to the loss of the hexose residue ( $m/z$  163 for **35**,  $m/z$  181  
424 for **36** and **37**), with the subsequent losses of  $H_2O$ ,  $CO$  and  $CO_2$  in the negative ion mode; and the  
425 sodium adduct in the positive ion mode ( $m/z$  349 for **35**,  $m/z$  367 for **36** and **37**).

426 Seven caffeic acid-hexosides, a synapic acid-hexosides, a dihydrocaffeic acid-hexoside and a  
427 *p*-coumaric acid-hexoside have been previously reported in green lettuce cultivars (Abu-Reidah et  
428 al., 2013). In the present work, one more caffeic acid-hexoside, a dihydrocaffeic acid-hexoside and  
429 three synapic acid-hexosides were identified in the butterhead lettuce cultivar.

430 Peaks **38** ( $R_t= 11.81$  min,  $\lambda_{max}= 307$  nm), **39** ( $R_t= 14.47$  min) and **40** ( $R_t= 16.48$  min) were  
431 tentatively proposed as isomers of ferulic acid methyl esters. According to previous data (Abu-  
432 Reidah et al., 2013; Gómez-Romero, María et al., 2011), these compounds showed demethylated  
433 fragment ions at  $m/z$  192 ( $[M-H-CH_3]^-$ ) and  $m/z$  177 ( $[M-H-2CH_3]^-$ ), which is characteristic of the

434 methoxylated cinnamic acids. Two of these isomers of ferulic acid methyl esters have been  
435 previously reported in green lettuce cultivars.

### 436 3.1.2. Hydroxybenzoic derivatives

437 Hydroxybenzoic derivatives were not detected in the positive ion mode. Thus, no peaks were  
438 detected in the chromatograms extracted from the TIC MS scan chromatogram at the protonated  
439 molecule or the sodium adduct masses of the hydroxybenzoic derivatives observed in the negative  
440 ion mode. Only one of the two previously reported in green lettuce cultivars (Abu-Reidah et al.,  
441 2013) isomers of hydroxybenzoic acid (**41**: Rt= 4.67 min) and dihydroxybenzoic acid (**42**: Rt= 5.42  
442 min) were detected at  $m/z$  137 and  $m/z$  153 respectively (Fig. 2S in the supplementary material).  
443 Their corresponding decarboxylated ions were also observed at  $m/z$  93 and  $m/z$  109 respectively.

444 Several hydroxybenzoic glycoside esters were characterized according to their MS data and  
445 fragmentation pattern by the neutral loss of the glycosidic moiety. Hydroxybenzoic acid-hexosides  
446 (**43**, Rt= 4.22 min; **44**, Rt= 5.15 min) yielded the deprotonated ion at  $m/z$  299 and the product ions  
447 due to losses of the hexose residue ( $m/z$  137) and CO<sub>2</sub> ( $m/z$  93). Dihydroxybenzoic acid-hexosides  
448 (**45**, Rt= 2.49 min; **46**, Rt= 2.69 min; **47**, Rt= 3.74 min; **48**, Rt= 3.91 min; **49**, Rt= 4.48 min; **50**, Rt=  
449 4.68 min) produced the deprotonated molecule at  $m/z$  315 (base peak), an odd electron product ion  
450 at  $m/z$  152 corresponding to the loss of hexose plus H (163 *u*), an even electron ion at  $m/z$  153 due  
451 to the loss of hexose (Fig. 2S in the supplementary material), the dehydrated ion at  $m/z$  135, and the  
452 decarboxylated ion at  $m/z$  109, in agreement with bibliography (Abu-Reidah et al., 2013). Hence,  
453 one more hydroxybenzoic acid-hexoside and four more dihydroxybenzoic acid-hexosides are here  
454 detected in butterhead lettuce than in previous studies on different lettuce cultivars. The release of  
455 such unusual losses was also observed for gallic acid-hexoside isomers. Thus, peaks **51** (Rt=2.80  
456 min), **52** (Rt=2.88 min) and **53** (Rt=6.61 min) were tentatively proposed as gallic acid-hexosides,  
457 since they yielded the deprotonated molecule at  $m/z$  331 (base peak) (Fig. 3S in the supplementary  
458 material), and an odd electron product ion at  $m/z$  168, corresponding to the loss of hexose plus H  
459 (163 *u*), an even electron ion at  $m/z$  169 due to the loss of hexose, and [gallic acid-H-CO<sub>2</sub>]<sup>-</sup> at  $m/z$

460 125. Two isomers of gallic acid-hexoside have been detected previously only in the lettuce cv. baby  
461 (Abu-Reidah et al., 2013).

462 Aside from the loss of the hexose moiety, syringic acid-hexoside (**54**,  $R_t= 5.90$  min,  $m/z$  359)  
463 showed subsequent losses of  $\text{CH}_3$  from the methoxy groups of the aglycone and  $\text{CO}_2$  ( $m/z$  182, 153,  
464 138 and 123), as previously observed in literature (Abu-Reidah et al., 2013; Gómez-Romero, María  
465 et al., 2011).

466 In agreement with previous studies (Abu-Reidah et al., 2013), compounds **55** ( $R_t= 17.09$   
467 min) and **56** ( $R_t= 24.83$  min) showing a deprotonated molecule at  $m/z$  451 were tentatively assigned  
468 as hydroxybenzoyl-gallic acid-hexosides (Fig. 3S in the supplementary material). The high energy  
469 function yielded the fragment ion corresponding to the deprotonated gallic acid-hexoside at  $m/z$   
470 331, after the loss of the hydroxybenzoyl moiety (120  $u$ ). As well, product ions due to successive  
471 losses of  $\text{H}_2\text{O}$  at  $m/z$  313, hexose plus H at  $m/z$  168 and  $\text{CO}_2$  at  $m/z$  124 were observed. A similar  
472 pattern was found for the hydroxybenzoyl-dihydroxybenzoic acid-hexosides (**57**,  $R_t= 17.68$  min;  
473 **58**,  $R_t= 19.41$  min; **59**,  $R_t= 23.64$  min; **60**,  $R_t= 26.88$  min,  $\lambda_{\text{max}}= 256, 335$  nm; **61**,  $R_t= 27.09$  min)  
474 detected in the extracted trace at  $m/z$  435 (Fig. 3S in the supplementary material). For peak **59**, only  
475 the deprotonated molecule was detected due to its low concentration in the extract. All other  
476 isomers yielded the fragment ions corresponding to [dihydroxybenzoic acid-hexoside-H] $^-$  at  $m/z$   
477 315, and the subsequent losses of  $\text{H}_2\text{O}$  at  $m/z$  297 and hexose plus H at  $m/z$  152 and  $\text{CO}_2$  at  $m/z$  108.  
478 Peaks **58** and **61** showed the product ion [dihydroxybenzoic acid-H] $^-$  due to an even electron ion at  
479  $m/z$  153 (loss of hexose), instead of the odd electron product ion at  $m/z$  152. Besides, peaks **57**, **60**  
480 and **61**, yielded the fragment ion [hydroxybenzoic acid-H] $^-$  at  $m/z$  137 and its corresponding  
481 decarboxylation ion at  $m/z$  93. This behaviour agrees with that observed for hydroxycinnamic acid  
482 glycosides above and in literature (Clifford et al., 2007), which suggest that both, the  
483 hydroxybenzoic acid moiety and the dihydroxybenzoic acid moiety, are attached through their  
484 phenolic hydroxyl to different positions of the same hexose molecule. Just one isomer of

485 hydroxybenzoyl-gallic acid-hexoside and two isomers of hydroxybenzoyl-dihydroxybenzoic acid-  
486 hexosides have been previously characterized only in cv. baby lettuce (Abu-Reidah et al., 2013).

### 487 **3.1.3. Hydroxyphenylacetic derivatives**

488 Taking into account the MS data, the fragmentation patterns observed for hydroxybenzoic  
489 acid in the negative ion mode and bibliography (Abu-Reidah et al., 2013; Gómez-Romero, María et  
490 al., 2011), 4-hydroxyphenylacetic acid was tentatively assigned to peak **62** (Rt= 5.60 min) (Fig. 4S  
491 in the supplementary material), which yielded the deprotonated molecule at  $m/z$  151 and fragment  
492 ions due to the loss of CO at  $m/z$  123 and CO<sub>2</sub> at  $m/z$  107, showing the typical decarboxylation of  
493 phenolic acids. Likewise, peak **63** (Rt= 5.20 min,  $\lambda_{max}$ = 270, 276 nm) observed in the extracted  
494 trace at  $m/z$  313, produced the same decarboxylation ions, and a fragment ion at  $m/z$  151 due to  
495 deprotonated 4-hydroxyphenylacetic acid obtained after the loss of a hexose moiety (Fig. 4S in the  
496 supplementary material). Thus, it was proposed as 4-hydroxyphenylacetic acid-hexoside. Both  
497 compounds have been previously detected in green lettuce cultivars (Abu-Reidah et al., 2013).

## 498 **3.2. Flavonoids**

### 499 **3.2.1. Flavonols**

500 Thirteen quercetin glycosides (**64-76**) and four kaempferol glycosides (**77-80**) were detected  
501 and identified on the basis of their mass spectral data, comparison with available standards, and  
502 literature. Flavonol monoglycoside mass spectra in the positive mode showed the protonated  
503 molecule  $[M+H]^+$ , the sodium adduct ion  $[M+Na]^+$  and the protonated aglycone ion  $[Y_0]^+$  as a result  
504 of the loss of the sugar or organic acid residue (losses: 146 *u*, rhamnosyl residue; 162 *u*, hexosyl  
505 residue; 176 *u*, glucuronic residue; 178 *u*, gluconic residue; 248 *u*, malonyl-hexosyl residue; 324 *u*,  
506 di-hexosyl residue; 338 *u*, glucuronic + hexosyl residue; 410 *u*, hexosyl + malonyl-hexosyl residue;  
507 424 *u*, glucuronic + malonyl-hexosyl residue). In the mass spectrum of flavonol diglycosides, a  
508 fragment  $[Y_1]^+$  due to the loss of the first sugar or organic acid unit was also observed. In the  
509 negative mode, the high energy function product ions corresponding to quercetin at  $m/z$  300 (odd  
510 electron ion) and/or 301 (even electron ion) were detected (Fig. 4S in the supplementary material),

511 as observed in MS/MS elsewhere (Abu-Reidah et al., 2013). Regarding this, compounds **64** (Rt=  
512 17.16 min,  $\lambda_{\max}$ = 279, 344 nm), **65** (Rt= 18.03 min,  $\lambda_{\max}$ = 252, 367 nm) and **66** (Rt= 20.25 min,  
513  $\lambda_{\max}$ = 252, 330 nm) were identified as quercetin-3-*O*-hexosides on the basis of their protonated  
514 molecule at  $m/z$  465 and a high energy function product ion at  $m/z$  303, which indicates cleavage of  
515 a hexosyl group. This fragmentation pattern and chromatographic retention time of the reference  
516 standard confirmed that compound **66** was quercetin-3-*O*-galactoside. Two isomers of quercetin  
517 hexose have been previously described in lettuce (Abu-Reidah et al., 2013; Becker, Klaering,  
518 Schreiner, Kroh, & Krumbein, 2014; Jeong et al., 2015; Lin et al., 2012; Llorach et al., 2008; Mai &  
519 Glomb, 2013; Marin et al., 2015; Pepe et al., 2015; Romani et al., 2002; Santos et al., 2014; Sofo,  
520 Lundegårdh, Mårtensson, Manfra, Pepe, Sommella et al., 2016).

521 Compound **67** (Rt= 18.44 min,  $\lambda_{\max}$ = 254, 349 nm) was identified as quercetin-3-*O*-  
522 glucuronide because of  $[M+H]^+$  at  $m/z$  479,  $[M+Na]^+$  at  $m/z$  501 and  $[Y_0]^+$  at  $m/z$  303, which  
523 indicated the loss of a glucuronic residue in the positive mode (Fig. 2). Similarly, in the negative  
524 mode, the molecule  $[M-H]^-$  at  $m/z$  477 yielded  $[Y_0]^-$  at  $m/z$  301; the loss of 176 *u* pointed out the  
525 presence of a glucuronic residue (Fig. 2). The presence of quercetin-3-*O*-glucuronide in lettuce had  
526 been previously confirmed by nuclear magnetic resonance analysis (DuPont, Mondin, Williamson,  
527 & Price, 2000; Mai & Glomb, 2013). The glucuronic group was also observed in compound **68** (Rt=  
528 9.50 min,  $\lambda_{\max}$ = 256, 352 nm) and compound **69** (Rt= 10.58 min), which gave  $[M+H]^+$  at  $m/z$  641,  
529  $[M+Na]^+$  at  $m/z$  663, and  $[Y_0]^+$  at  $m/z$  303 in positive mode, and peak **69**, also  $[Y_1]^+$  at  $m/z$  465. In  
530 the negative mode, both compounds presented similar ionization and fragmentation pattern:  $[M-H]^-$   
531 at  $m/z$  639,  $[Y_1]^-$  at  $m/z$  463 and  $[Y_0]^-$  at  $m/z$  300 (odd electron ion) and/or 301 (even electron ion).  
532 Moreover, the loss of 162 *u* revealed the cleavage of a hexoxyl group, therefore these flavonols  
533 were assigned to quercetin hexose-glucuronide isomers, which had been already described in baby,  
534 romaine and iceberg cultivars (Abu-Reidah et al., 2013).

535 Compounds **70** (Rt= 21.52 min,  $\lambda_{\max}$ = 255, 352 nm), **71** (Rt= 22.03 min,  $\lambda_{\max}$ = 252, 364  
536 nm) and **72** (Rt= 23.69 min) were identified as quercetin malonylhexoside isomers since they

537 presented  $[M+H]^+$  at  $m/z$  551,  $[M+Na]^+$  at  $m/z$  573, and  $[Y_0]^+$  at  $m/z$  303 due to the loss of the  
538 malonylhexosyl moiety in the positive ion mode; and  $[M-H]^-$  at  $m/z$  549,  $[Y_0]^-$  at  $m/z$  301 (Fig. 4S  
539 in the supplementary material),  $[M-H-CO_2]^-$  at  $m/z$  505 (base peak) in the negative ion mode. The  
540 neutral loss of  $CO_2$  is characteristic of compounds presenting the malonyl group, as previously  
541 reported (Abu-Reidah et al., 2013). This fact is due to in-source fragmentation, which can affect the  
542 correct identification of the deprotonated molecule of interest, because the relative abundance of  
543  $[M-H]^-$  ion could be lower than the product ion  $[M-H-CO_2]^-$  as occurred with these peaks. This  
544 particularly labile group could be partially lost during ion transfer from a higher-pressure region of  
545 the source to a lower-pressure region (Katta, Chowdhury, & Chait, 1991), as observed for peak **70**  
546 (0.4 % RA), peak **71** (11 % RA) and peak **72** (0.4 % RA). The identification of compound **70** was  
547 also confirmed by the presence of  $[2M-H]^-$  ion. Quercetin-3-*O*-(6''-*O*-malonyl)-glucoside has been  
548 reported in lettuce in several publications (Becker et al., 2014; DuPont et al., 2000; Ferreres, Gil,  
549 Castañer, & Tomás-Barberán, 1997; Heimler, Isolani, Vignolini, Tombelli, & Romani, 2007;  
550 Llorach et al., 2008; Mai & Glomb, 2013; Marin et al., 2015; Ribas-Agustí et al., 2011; Romani et  
551 al., 2002; Santos et al., 2014), and confirmed by NMR analysis (DuPont et al., 2000; Ferreres et al.,  
552 1997). Two isomers of quercetin malonylglucoside were already described in different lettuce  
553 varieties (Abu-Reidah et al., 2013; Lin et al., 2012). The presence of three quercetin  
554 malonylhexoside isomers in lettuce is described for the first time in the present study.

555 Compound **73** ( $R_t=$  11.51 min,  $\lambda_{max}=$  253, 355 nm) was identified as quercetin-3-*O*-(6''-*O*-  
556 malonyl)-glucoside-7-*O*-glucuronide, which has been previously described in lettuce (Abu-Reidah  
557 et al., 2013; Llorach et al., 2008; Santos et al., 2014). In the positive ion mode,  $[M+H]^+$  at  $m/z$  727,  
558  $[M+Na]^+$  at  $m/z$  749, and the fragment ions  $[Y_1]^+$  at  $m/z$  479 and  $[Y_0]^+$  at  $m/z$  303 indicated the loss  
559 of a malonyl-glucosyl group followed by a glucuronic group. In the negative ion mode, the neutral  
560 loss of  $CO_2$  yielding  $[M-H-CO_2]^-$  at  $m/z$  681 confirmed the presence of a malonyl residue in the  
561 molecular structure; as well as the high energy function product ions at  $m/z$  300 (odd electron ion)  
562 and/or 301 (even electron ion) (Fig. 4S in the supplementary material), the presence of quercetin.

563 Similarly, compound **74** (Rt= 13.82 min,  $\lambda_{\max}$ = 253, 350 nm) also contained a malonyl residue  
564 since its base peak in the negative mode was  $[M-H-CO_2]^-$  at  $m/z$  667. The deprotonated molecule  
565 at  $m/z$  711 was also present and  $[Y_0]^-$  at  $m/z$  300 (odd electron ion) and/or 301 (even electron ion)  
566 (Fig. 4S in the supplementary material) indicated that the aglycone was quercetin. The positive ion  
567 mode yielding  $[M+H]^+$  at  $m/z$  713,  $[M+Na]^+$  at  $m/z$  735, and the fragment ions  $[Y_1]^+$  at  $m/z$  465 and  
568  $[Y_0]^+$  at  $m/z$  303 confirmed the cleavage of malonylhexosyl group followed by a hexosyl group.  
569 Thus, compound **74** was tentatively assigned to quercetin-3-*O*-(6''-*O*-malonyl)-glucoside-7-*O*-  
570 glucoside, which has been previously reported in lettuce (Abu-Reidah et al., 2013; Llorach et al.,  
571 2008; Santos et al., 2014), and confirmed by NMR analysis (Ferrerres et al., 1997).

572 Compounds **75** (Rt= 12.18 min) and **76** (Rt= 16.07 min) presented the same monoisotopic  
573 molecular mass for  $[M+H]^+$  at  $m/z$  627.1580 (C<sub>27</sub>H<sub>31</sub>O<sub>17</sub>) and  $[M-H]^-$  at  $m/z$  625.1405 (C<sub>27</sub>H<sub>29</sub>O<sub>17</sub>),  
574 and  $[M+Na]^+$  at  $m/z$  649.1381 (C<sub>27</sub>H<sub>30</sub>O<sub>17</sub>Na). The presence of  $[Y_0]^+$  at  $m/z$  303 and  $[Y_0]^-$  at  $m/z$  301  
575 (Fig. 4S in the supplementary material) in the positive and negative ion modes, respectively,  
576 disclosed that the aglycone was quercetin. However, these compounds followed different  
577 fragmentation patterns. Peak **75** yielded  $[Y_1]^-$  at  $m/z$  463 due to the loss of a hexosyl moiety (162  
578 *u*), and revealing that  $[Y_0]^-$  was obtained from the loss of a second hexosyl residue. Thus,  
579 compound **75** was assigned as a quercetin-*O*-di-hexoside. Instead, peak **76** yielded  $[Y_1]^-$  at  $m/z$  447  
580 due to the loss of a gluconic moiety (178 *u*), and disclosing a subsequent loss of a rhamnosyl moiety  
581 (146 *u*) to achieve  $[Y_0]^-$ . Peak **75** was tentatively identified as quercetin-di-glucoside, which has  
582 been previously reported in green lettuce (Santos et al., 2014). Peak **76** was tentatively proposed as  
583 quercetin-*O*-rhamnosyl-gluconide, which is here reported for the first time to the author's  
584 knowledge.

585 Regarding kaempferol conjugates, compound **77** (Rt= 25.27 min,  $\lambda_{\max}$ = 265, 347 nm) was  
586 identified as kaempferol-3-*O*-(6'-*O*-malonyl)-glucoside, which has been already found in different  
587 lettuce cultivars (Heimler et al., 2007). In the positive mode,  $[M+H]^+$  at  $m/z$  535,  $[M+Na]^+$  at  $m/z$   
588 557, and the fragment ions and  $[Y_0]^+$  at  $m/z$  287 revealed the cleavage of a malonyl-glucosyl group.

589 In the negative mode,  $[M-H]^-$  at  $m/z$  533,  $[Y_0]^-$  at  $m/z$  285,  $[M-H-CO_2]^-$  at  $m/z$  489 confirmed the  
590 presence of the malonyl glucosyl moiety in the molecule (Fig. 4S in the supplementary material).  
591 Regarding the aglycone, kaempferol and the flavone luteolin are isobaric, but their conjugates can  
592 be distinguished on the basis of their MS and MS/MS data. In the positive low energy function,  
593 kaempferol derivatives yield  $[Y_0]^+$  as the base peak or  $[M+H]^+$  as the base peak plus an intense  
594  $[Y_0]^+$ , whereas luteolin derivatives give as the base peak  $[M+H]^+$  or  $[M+H-H_2O]^+$ , and  $[Y_0]^+$  does  
595 not appear or present low relative abundance. In the negative low energy function, both compounds  
596 yield  $[M-H]^-$  or  $[M-H-CO_2]^-$  (in the case of malonyl glycosides) as the base peak, but in the  
597 negative high energy function, kaempferol conjugates give the base peak  $[Y_0]^-$ , whereas luteolin  
598 compounds yield the base peak  $[M-H]^-$  or  $[M-H-CO_2]^-$  and an intense  $[Y_0]^-$ , or  $[Y_0]^-$  as the base  
599 peak and an intense  $[M-H]^-$  with relative abundance higher than 50% RA. Moreover, several minor  
600 monoisotopic product ions at  $m/z$  217.0501 ( $C_{12}H_9O_4$ ), 199.0395 ( $C_{12}H_7O_3$ ), 175.0395 ( $C_{10}H_7O_3$ )  
601 and 133.0290 ( $C_8H_5O_2$ ) are characteristic of luteolin, and helps to distinguish it from its kaempferol  
602 isomers (Abu-Reidah et al., 2013; Gómez-Romero, María et al., 2011). In this sense, these fragment  
603 ions did not appear in the negative high energy MS spectra of peak **77**, suggesting that it is a  
604 kaempferol derivative. Moreover, this identification was also supported by the base peaks yielded in  
605 the positive low energy and the negative high energy functions,  $[Y_0]^+$  and  $[Y_0]^-$  respectively, as well  
606 as its UV-visible spectra, and elution order since kaempferol isomers elute later than luteolin  
607 isomers on endcapped  $C_{18}$  packings.

608 Two isomers (**78**:  $R_t=$  23.90 min; **79**:  $R_t=$  26.43 min) were detected in the extracted MS  
609 chromatogram at  $m/z$  449 and 447 in the positive and negative ion modes respectively, which  
610 yielded the protonated ion,  $[M+Na]^+$  at  $m/z$  471 and  $[Y_0]^+$  at  $m/z$  287 in the positive ion mode, and  
611 the deprotonated molecule and  $[Y_0]^-$  at  $m/z$  285 in the negative ion mode (Fig. 4S in the  
612 supplementary material); revealing the loss of a hexosyl residue and the presence of kaempferol or  
613 luteolin aglycone. The base peaks yielded in the positive low energy and the negative high energy  
614 functions were  $[Y_0]^+$  and  $[Y_0]^-$  respectively, and no characteristic minor product ions of luteolin

615 were detected in the negative high energy function, therefore the aglycone was tentatively identified  
616 as kaempferol. Compound **78** was identified unambiguously as kaempferol-3-*O*-glucoside by  
617 comparison with its standard, whereas compound **79** as kaempferol-hexoside. Kaempferol-3-*O*-  
618 glucoside is the only kaempferol-hexoside that has been previously detected in several lettuce  
619 cultivars (Alarcón-Flores et al., 2016).

620 Compound **80** ( $R_t = 22.34$  min,  $\lambda_{\max} = 265, 332$  nm) was identified as kaempferol-3-*O*-  
621 glucuronide, which has been previously found in lettuce in literature (Jeong et al., 2015). This  
622 compound yielded  $[M+H]^+$  at  $m/z$  463,  $[M+Na]^+$  at  $m/z$  485 and  $[Y_0]^+$  at  $m/z$  287 in the positive  
623 mode; and  $[M-H]^-$  at  $m/z$  461 and  $[Y_0]^-$  at  $m/z$  285 in the negative mode (Fig. 4S in the  
624 supplementary material). The observed loss of 176  $u$  pointed out the presence of a glucuronic  
625 residue. Besides, the presence of the base peaks  $[Y_0]^+$  and  $[Y_0]^-$  in the positive low energy and the  
626 negative high energy functions respectively, and the absence of luteolin characteristic minor  
627 product ions in the negative high energy function, supports the proposed identification for this  
628 compound.

629 Peak **81** ( $R_t = 27.08$  min) presented the protonated and deprotonated molecules at  $m/z$  287  
630 and 285 in the positive and the negative ion modes respectively (Fig. 4S in the supplementary  
631 material), which yielded fragment ions characteristics of kaempferol or luteolin aglycones (Abad-  
632 García et al., 2009), suggesting that both compounds were eluting overlapped in this peak. To the  
633 author's knowledge, kaempferol aglycone has not been previously found in lettuce, but in escarole  
634 (Asteraceae) (Llorach et al., 2008).

### 635 3.2.2. Flavones

636 Four luteolin glycosides (**82-85**) and four apigenin conjugates (**86-89**) were detected and  
637 identified on the basis of mass spectral data, comparing with available standards and bibliographic  
638 sources. Compound **82** ( $R_t = 19.82$  min,  $\lambda_{\max} = 255, 347$  nm) was identified unambiguously as  
639 luteolin-7-*O*-glucoside by comparison with its standard, which showed the deprotonated molecule  
640 at  $m/z$  447,  $[2M-H]^-$  at  $m/z$  895,  $[Y_0]^-$  at  $m/z$  285 (Fig. 4S in the supplementary material), and

641 luteolin characteristic minor product ions at  $m/z$  217, 199 and 175 in the negative ion mode; and the  
642 protonated molecule at  $m/z$  449,  $[M+Na]^+$  at  $m/z$  471,  $[Y_0]^+$  at  $m/z$  287, and intense fragment ions at  
643 153 and 135 in the positive mode. Luteolin-7-*O*-glucoside has been previously described in lettuce  
644 cultivars (Abu-Reidah et al., 2013; Alarcón-Flores et al., 2016; Lin et al., 2012).

645 Compound **83** ( $R_t=$  17.45 min,  $\lambda_{max}=$  253, 348 nm) was assigned to luteolin-7-*O*-  
646 glucuronide regarding the protonated molecule yielded at  $m/z$  463,  $[M+Na]^+$  at  $m/z$  485 and  $[Y_0]^+$  at  
647  $m/z$  287, which revealed the cleavage of a glucuronic residue. In the negative high energy function,  
648 compound **83** yielded the corresponding deprotonated molecule at  $m/z$  461,  $[Y_0]^-$  at  $m/z$  285 , as  
649 well as some minor fragment ions at  $m/z$  217, 199, 175, 151 and 133 (Fig. 4S and 7S in the  
650 supplementary material), which distinguished luteolin conjugates from its kaempferol isomers  
651 (Abu-Reidah et al., 2013; Gómez-Romero, María et al., 2011). This identification was supported by  
652 its UV-visible spectrum, which followed the luteolin pattern; and its elution order on encapped C18  
653 packings, glucuronide conjugates elute earlier than their corresponding glucoside ones. Luteolin-7-  
654 *O*-glucuronide has been previously reported in lettuce (Abu-Reidah et al., 2013; DuPont et al.,  
655 2000; Lin et al., 2012; Mai & Glomb, 2013; Santos et al., 2014), and confirmed by NMR analysis  
656 (DuPont et al., 2000; Ferreres et al., 1997).

657 Compounds **84** ( $R_t=$  20.27 min) and **85** ( $R_t=$  21.17 min,  $\lambda_{max}=$  268, 351 nm) showed base  
658 peaks at  $m/z$  595 ( $[M+H]^+$ ) in the low energy function. Aside, compound **85** also presented the  
659 sodium adduct ( $m/z$  617), the fragment ions at  $m/z$  449 ( $[Y_1]^+$ ), and at  $m/z$  287 ( $[Y_0]^+$ ) in the high  
660 energy function in the positive ion mode. This fragmentation pattern revealed the loss of rhamnosyl  
661 group followed by a hexosyl group, which is in agreement with the fragment ions observed in the  
662 negative ion mode, i.e.  $[Y_1]^-$  at  $m/z$  447 and  $[Y_0]^-$  at  $m/z$  285 (Fig. 4S in the supplementary  
663 material). In the negative ion mode, both compounds yielded the deprotonated molecule as the base  
664 peak in both low and high energy functions, supporting their tentatively assignment as luteolin-  
665 rhamnosylhexoside. Compound **85** was tentatively identified as luteolin-7-*O*-rutinoside since it was  
666 the major compound and has been previously found in different lettuce cultivars (Llorach et al.,

667 2008). The second luteolin-rhamnosylhexoside (**84**) is here reported for the first time in lettuce to  
668 the authors' knowledge.

669         Regarding apigenin derivatives, the observation of neutral losses of the conjugated groups  
670 and the product ions at  $m/z$  271 and 269 in the positive and negative ion modes respectively,  
671 indicated the presence of apigenin in their structure (Fig. 4S in the supplementary material). Thus,  
672 compound **86** ( $R_t= 20.57$  min) showing a loss of 176  $u$  was identified as apigenin-glucuronide;  
673 compound **87** ( $R_t= 23.02$  min,  $\lambda_{max}= 259, 328$  nm) with a loss of 162  $u$ , as apigenin-glucoside; and  
674 compound **88** ( $R_t= 23.90$  min) with subsequent losses of 146  $u$  and 162  $u$ , as apigenin-  
675 rhamnosylhexoside, which is here reported for the first time in lettuce cultivars. Likewise,  
676 compound **89** ( $R_t= 26.99$  min) yielded the protonated and deprotonated molecules at  $m/z$  839 and  
677 837 and the corresponding apigenin aglycone ions in positive and negative ion modes respectively,  
678 showing a monoisotopic loss of 568.2731  $u$  ( $C_{25}H_{44}O_{14}$ ), however its identity was not able to be  
679 disclosed with the available spectral data. Apigenin-glucuronide (**86**) and apigenin-glucoside (**87**)  
680 have been already found in lettuce (Abu-Reidah et al., 2013; Alarcón-Flores et al., 2016). Alarcón-  
681 Flores et al. (2016) found an apigenin-*O*-derivative with the same fragmentation pattern as  
682 apigenin-rhamnosylhexoside (**88**) in different lettuce cultivars, as well as luteolin aglycone (**90**,  $R_t=$   
683 27.08 min). However, the apigenin conjugate (**89**) has not been previously reported.

### 684 3.2.3. Flavanones

685         A flavanone glycoside was detected and identified on the basis of its UV-visible spectrum  
686 and mass spectral data. Chromatographic peak **91** ( $R_t= 14.87$  min,  $\lambda_{max}= 284$  nm, shoulder at 329  
687 nm) in the negative mode yielded the base peaks  $[M-H]^-$  at  $m/z$  463 in the low energy function, and  
688 a fragment ion  $[^{1,3}A]^-$  at  $m/z$  151 and an intense ion  $[Y_0]^-$  at  $m/z$  287 (60% RA) in the high energy  
689 function (Fig. 3 and Fig. 5S in the supplementary material). In the positive ion mode,  $[M+H]^+$  at  $m/z$   
690 465 (60% RA),  $[M+Na]^+$  at  $m/z$  487 and a fragment ion  $[Y_0]^+$  at  $m/z$  289 (base peak) were detected  
691 (Fig. 3). Both fragment ions revealed the cleavage of a glucuronic group. Moreover, a minor  
692 fragment  $[^{1,3}A]^+$  at  $m/z$  153 in the positive ion mode contributed to confirm that the aglycone was

693 eriodictyol (Abad-García et al., 2009). Thus, compound **91** was identified as eriodictyol-*O*-  
694 glucuronide, which is reported for the first time in lettuce to our best knowledge.

### 695 **3.3. Coumarins**

696 Seven coumarins (**92-98**) were detected in butterhead lettuce cultivar. Chromatographic peak  
697 **92** (Rt= 6.50 min,  $\lambda_{\max}$ = 290, 340 nm) was identified as a 6,7-dihydroxycoumarin-6-*O*-glucoside  
698 (esculin) regarding its UV-visible spectrum and mass spectral data. In the positive ion mode, the  
699 protonated molecule at  $m/z$  341, the sodium adduct at  $m/z$  363 and  $[Y_0]^+$  at  $m/z$  179 were produced,  
700 indicating that a hexosyl group was present in the molecular structure. This was confirmed in the  
701 negative ion mode, where the deprotonated molecular at  $m/z$  339, the acetate adduct  $[M-H+AcO]^-$   
702 at  $m/z$  399 and  $[Y_0]^-$  at  $m/z$  177 were yielded (Fig. 5S in the supplementary material). Compound **92**  
703 also gave some minor fragment ions at  $m/z$  133 and 105 corresponding to the loss of CO<sub>2</sub> and CO  
704 successively (Fig. 8S in the supplementary material), which have been previously reported in  
705 literature (Abu-Reidah et al., 2013), and suggested that peak **92** was esculetin-6-*O*-glucoside.

706 Compounds **93** (Rt= 7.31 min), **94** (Rt= 10.23 min) and **95** (Rt= 12.02 min,  $\lambda_{\max}$ = 296, 330  
707 nm) presented the same protonated molecules at  $m/z$  179 and deprotonated molecules at  $m/z$  177  
708 (Fig. 5S in the supplementary material), as well as the same fragmentation pattern described above  
709 for esculin. Thus, they were tentatively identified as dihydrocoumarin isomers. Esculin and 6,7-  
710 dihydrocoumarin (**95**) have been already reported in lettuce and Asteraceae (Abu-Reidah et al.,  
711 2013; Schütz, Carle, & Schieber, 2006). In the same way, compounds **96** (Rt= 9.05 min), **97** (Rt=  
712 10.54 min) and **98** (Rt= 12.54 min) presented the same fragmentation patterns as the  
713 dihydrocoumarin isomers (Fig. 5S in the supplementary material), but their protonated molecules at  
714  $m/z$  295 and deprotonated molecules at  $m/z$  293 disclosed that the loss to yield the dihydrocoumarin  
715 ion was 116 *u*, due to a maloyl residue. Thus, these compounds were tentatively assigned as maloyl-  
716 dihydrocoumarin isomers. Regarding the elution order of the dihydrocoumarin and the maloyl-  
717 dihydrocoumarin isomers, the latter are probably the maloyl derivatives of the former, since the  
718 maloyl group increase the hydrophobicity of the molecule, and therefore, elute at higher retention

719 times in reverse-phase packings. To the authors' knowledge, maloyl-dihydrocoumarins are reported  
720 in lettuce and Asteracea for the first time.

### 721 **3.4. Hydrolysable tannins**

722 A tri-4-hydroxyphenylacetyl ester of a hexose (**99**,  $R_t= 27.09$  min) was detected in the  
723 extracted trace at  $m/z$  581 in the negative ion mode. This peak showed the characteristic  
724 fragmentation pattern previously described in literature (Abu-Reidah et al., 2013), yielding  
725 fragment ions at  $m/z$  295 ( $[(4\text{-hydroxyphenylacetic acid-hexose})\text{-H-H}_2\text{O}]^-$ ),  $m/z$  175 ( $[(4\text{-}$   
726  $\text{hydroxyphenylacetic acid-hexose})\text{-2H-H}_2\text{O-C}_6\text{H}_5\text{CH}_2\text{CO}]^-$ ),  $m/z$  151 ( $[4\text{-hydroxyphenylacetic}$   
727  $\text{acid-H}]^-$  (Fig. 4S in the supplementary material) and  $m/z$  143 ( $[(4\text{-hydroxyphenylacetic acid-}$   
728  $\text{hexose})\text{-2H-H}_2\text{O-OHC}_6\text{H}_4\text{CH}_2\text{COOH}]^-$  or  $[\text{hexose-H-2H}_2\text{O}]^-$ ). Four isomers of tri-4-  
729 hydroxyphenylacetyl-glucoside were found in several *Latuca* species (Abu-Reidah et al., 2013).

### 730 **3.5. Lignan derivatives**

731 Peak **100** ( $R_t= 21.00$  min), detected in the extracted MS chromatogram set at  $m/z$  417 in the  
732 negative ion mode (Fig. 5S in the supplementary material), yielded the fragment ion  $m/z$  359 due to  
733 the losses of two methyl moieties plus CO. In the positive ion mode, the corresponding protonated  
734 molecule was detected at  $m/z$  419. This compound was tentatively identified as syringaresinol,  
735 having not been found in lettuce cultivars before to the best of our knowledge. In relation to this  
736 compound, four syringaresinol-hexoses (**101**,  $R_t= 13.90$  min; **102**,  $R_t= 18.97$  min; **103**,  $R_t= 19.63$   
737 min; **104**,  $R_t= 23.30$  min) were detected in the extracted trace at  $m/z$  579 and 581 in the negative  
738 and positive ion modes. For peak **102**, only the corresponding deprotonated and protonated  
739 molecules were detected due to its low concentration in the extract. All other isomers yielded in the  
740 negative ion mode the fragment ions corresponding to the loss of the hexose residue ( $m/z$  417) (Fig.  
741 5S in the supplementary material), and the subsequent losses of  $\text{H}_2\text{O}$  ( $m/z$  399) or two methyl  
742 residues ( $m/z$  387) from the syringaresinol. In the positive ion mode, the sodium adducts ( $m/z$  603)  
743 and the fragment ion due to the loss of the hexose residue plus two  $\text{H}_2\text{O}$  ( $m/z$  383) were detected. In  
744 addition, three isomers of syringaresinol-acetylhexoses (**105**,  $R_t= 15.06$  min,  $\lambda_{\text{max}}= 205, 280$  nm;

745 **106**, Rt= 24.50 min; **107**, Rt= 24.63 min) were detected in the extracted trace at  $m/z$  621 in the  
746 negative ion mode, presenting the same aforementioned fragmentation pattern. In this sense, the  
747 fragment ions due to the loss of the acetylhexose residue ( $m/z$  417) (Fig. 5S in the supplementary  
748 material), and the successive losses of H<sub>2</sub>O ( $m/z$  399), and methyl residues ( $m/z$  402 (-CH<sub>3</sub>),  $m/z$   
749 387 (-2CH<sub>3</sub>) and  $m/z$  359 (-2CH<sub>3</sub>CO)) were observed, as well as other further fragments from the  
750 syringaresinol structure at  $m/z$  181, 166, 151 and 123 (Fig. 9S in the supplementary material).

751 Peaks **108** (Rt= 19.22 min), **109** (Rt= 19.39 min) and **110** (Rt= 19.82 min) were observed in  
752 the chromatogram set at  $m/z$  581 in the negative ion mode (Fig. 5S in the supplementary material).  
753 The MS spectra of these compounds disclosed that they presented the same fragmentation pattern as  
754 the above lignans, yielding the product ions due to the loss of the dimethoxyhexose moiety ( $m/z$   
755 359), and the subsequent losses of H<sub>2</sub>O ( $m/z$  341), and two methyl residues ( $m/z$  329) from the  
756 lariciresinol structure. Thus, these compounds were proposed to be isomers of dimethoxy-hexosyl-  
757 lariciresinol. Furthermore, a dimethoxy-dihexosyl-lariciresinol isomer (**111**: Rt= 16.37 min) was  
758 also tentatively identified according to the presence of the deprotonated ion at  $m/z$  743 and the  
759 fragment ion due to the loss of a hexose residue at  $m/z$  581 in its negative ion MS spectra, which  
760 yielded further product ions following the same fragmentation pattern of dimethoxy-hexosyl-  
761 lariciresinol. In lettuce cultivars, only one isomer of syringaresinol-hexose (syringaresinol- $\beta$ -D-  
762 glucoside) and dimethoxy-hexosyl-lariciresinol have been previously reported (Abu-Reidah et al.,  
763 2013).

764 In conclusion, the UHPLC-DAD-ESI-QToF/MS<sup>E</sup> approach demonstrates to be a useful tool  
765 for the characterization of phenolic compounds in complex plant matrices.

## 766 Acknowledgements

767 The authors gratefully acknowledge the Agencia Nacional de Promoción Científica y  
768 Tecnológica (project number PICT-2008-1724) and the Consejo Nacional de Investigaciones  
769 Científicas y Técnicas (CONICET) (project number PIP 0007) from Argentina for the financial

770 support. Gabriela Elena Viacava thanks CONICET and Asociación Universitaria Iberoamericana de  
771 Postgrado (AUIP) for her Ph.D. grants.

**Figure captions**

897 **Fig. 1.** Chemical structures of phenolic compounds found in butterhead lettuce cultivar.  
898 Abbreviations for the phenolic moieties: C, caffeoyl; pCo, *p*-coumaroyl; F, feruloyl;  
899 dhC, dihydrocaffeoyl; Sp, sinapoyl; 4-OH-Bz, 4-hydroxybenzoyl; 3,4-diOH-Bz, 3,4-  
900 dihydroxybenzoyl; Gal, galloyl; Syr, syringoyl; 4-OH-PhAc, 4-hydroxyphenylacetoyl;  
901 Que, quercetin ( $Z_1=OH$ ,  $Z_2=OH$ ); Kaemp, kaempferol ( $Z_1=H$ ,  $Z_2=OH$ ); Lut, luteolin  
902 ( $Z_1=OH$ ,  $Z_2=H$ ); Api, apigenin ( $Z_1=H$ ,  $Z_2=H$ ); 6,7-diOH-Cou, 6,7-dihydroxycoumarin.  
903 Abbreviations for the non-phenolic moieties: Q, quinic acid; Tar, tartaric acid, Mal,  
904 malic acid; Mln, malonic acid; Gler, glucuronic acid; Gln, gluconic acid; Hex, hexose;  
905 Rha, rhamnose; Rut, rutinose (rhamnosylglucose). R, R<sub>1</sub>, R<sub>2</sub>, R<sub>3</sub>, R<sub>4</sub> and R<sub>5</sub> in non-  
906 phenolic moieties can be esterified in position X of phenolic acids or etherified with  
907 phenolic OH groups.

908 **Fig. 2.** Low (F1) and high (F2) energy function MS spectra in the negative and positive ion  
909 mode of quercetin-3-*O*-glucuronide. ESI, electrospray ionization.

910 **Fig. 3.** Low (F1) and high (F2) energy function MS spectra in the negative and positive ion  
911 mode of eriodictyol-*O*-glucuronide. ESI, electrospray ionization.

913 **Supplementary material**

914 **Fig. 1S.** Low energy function (F1) base peak chromatograms in positive and negative ion modes  
915 and DAD chromatograms at 280 and 370 nm of the butterhead lettuce cultivar.

916 **Fig. 2S.** Butterhead lettuce cultivar chromatograms extracted from the TIC-MS scan  
917 chromatogram in negative ion mode at  $m/z$  353, 341, 385 and 153 of the low energy  
918 function (F1). Chromatographic peaks are numbered as in Tables 1.

919 **Fig. 3S.** Butterhead lettuce cultivar chromatograms extracted from the TIC-MS scan  
920 chromatogram in negative ion mode at  $m/z$  337, 311, 331, 451 and 435 of the low energy  
921 function (F1). Chromatographic peaks are numbered as in Tables 1.

922 **Fig. 4S.** Butterhead lettuce cultivar chromatograms extracted from the TIC-MS scan  
923 chromatogram in negative ion mode at  $m/z$  151 of the low energy function (F1), and at  
924  $m/z$  301, 285 and 269 of the high energy function (F2). Chromatographic peaks are  
925 numbered as in Tables 1.

926 **Fig. 5S.** Butterhead lettuce cultivar chromatograms extracted from the TIC-MS scan  
927 chromatogram in negative ion mode at  $m/z$  287, 177 and 581 of the low energy function  
928 (F1), and at  $m/z$  417 of the high energy function (F2). Chromatographic peaks are  
929 numbered as in Tables 1.

930 **Fig. 6S.** Low (F1) and high (F2) energy function MS spectra in the negative and positive ion  
931 mode of *5-trans-O*-caffoylquinic acid. ESI, electrospray ionization.

932 **Fig. 7S.** Low (F1) and high (F2) energy function MS spectra in the negative and positive ion  
933 mode of luteolin-7-*O*-glucuronide. ESI, electrospray ionization.

934 **Fig. 8S.** Low (F1) and high (F2) energy function MS spectra in the negative and positive ion  
935 mode of esculetin-6-*O*-glucoside. ESI, electrospray ionization.

936 **Fig. 9S.** Low (F1) and high (F2) energy function MS spectra in the negative and positive ion  
937 mode of syringaresinol-acetylhexose. ESI, electrospray ionization.

## 1 Table 1

2 Retention times, UV-visible maxima and MS<sup>E</sup> data of polyphenols identified by UHPLC-DAD-ESI-Q-ToF/MS in the butterhead lettuce cultivar.<sup>a, b, c</sup>
