Abstract: Although the technological revolution of recent decades has produced undeniable advances, it has also generated problems derived from new forms of human communication, especially among the younger population. This is the case with cyber dating violence, a problem that affects between 12% and 56% of young couples, making the need for preventive intervention patently evident. This study attempts to fill a gap in the literature in this field, carrying out a systematic review of universal cyber dating violence prevention programs, analyzing their characteristics and the evidence provided of their effectiveness. Following the PRISMA method, only 3 programs met the inclusion criteria: the DARSI program, the Dat-e Adolescence program and the Brief Incremental Theory of Personality (ITP) adolescent dating violence prevention program. All were reported to be effective, based on different indicators. Given the small body of work published to date and the limitations of the aforementioned programs, future research should aim to design and validate a greater number of programs that serve as tools for addressing this problem in a timely manner, in order to avoid not only the serious consequences it has for victims, but also its escalation towards adulthood.

Keywords: cyber abuse, teenagers, youth, relationships, preventive interventions

Introduction

The technological revolution of recent decades has profoundly changed the way in which we communicate and interact in our society,¹ especially for young people. Most of the adolescents use the Internet as a way for socializing² and, as Romo-Tobón, Vázquez-Sánchez, Rojas-Solis and Alvidrez³ point out, virtual social networks have become essential tools for adolescents, who use them to form groups or initiate social relationships,⁴ maintain contact with their peers,⁵ experience love and partnership⁶ and even initiate romantic relationships.⁷

Although the benefits of these technological advances are undeniable, the truth is that they also encourage the emergence of new forms of harassment, control and abuse,⁸ making individuals more accessible and vulnerable to personal intrusion,⁹ as well as to other types of violence, due to the connections between online and offline violence.¹⁰ One example of this is the context of dating, where so-called cyber violence can occur. Cyber dating violence has been defined as a set of repeated behaviors aimed at controlling, undermining, or causing harm to the partner^{1,11} or ex-partner,¹² and includes behaviors such as frequently visiting his/her profile on social networks, sending insulting or threatening messages, spreading negative information about her/him, and stealing or misusing her/his passwords, etc.^{11,13,14}

This is a particularly worrying problem among teenage couples, not only because they are at a very vulnerable stage, but also because of the prevalence data reported by authors studying this phenomenon, who found that between 12% and 56% of teenagers who are or have been in a romantic relationship, claim to have suffered from this problem.¹⁵ More specifically, in a recent study with 919 Spanish adolescents (aged 12–18 years), “almost half of the adolescents (44.1%) indicated having occasionally displayed some cyber-control behavior toward their partners, and more than one tenth of them (11.7%) had done so more frequently”.¹⁶ However, prevalence data usually vary depending on if they refer to victimization or to perpetration. In this sense, in a relatively recent review including 12 studies, victimization rates ranging from 12% to 56% were observed in adolescents, and perpetration rates of between 12% and 54%.¹⁷ Furthermore, the percentages are nuanced when referring to specific types of cyber violence behaviors. Thus, in a study carried out by Borrajo et al¹⁸ in which direct aggressions were differentiated from control behaviors, it was found that 10.6% admitted having committed direct cyber-aggressions against their partner, and this percentage rose to 82% when referring to cyber-control behaviors. Similarly, the prevalence of victimization ranged from 14% to 75% depending on whether it referred to direct cyber-aggression or cyber-control. In any case, and even taking into account that data can differ depending on the type of cyber violence the focus is on, the truth is that it is a problem that needs attention, especially in adolescence.

Adolescence is usually the time when people begin to engage in romantic relationships,¹⁹ although it is true that on many occasions these beginnings are characterized by a misperception of what a healthy romantic relationship actually is. As Wolfe et al²⁰ state, “... a considerable number of youths engage in acts with romantic partners that may be far from harmless and point to the need to provide guidance as adolescents navigate this important course”. (p. 280). Adolescents often have a biased perception of love, accepting or normalizing attitudes and behaviors that are, in fact, the first warning signs of the aforementioned problem. To give an example, they consider revealing their mobile phone or social network password to their partner to be proof of their love. These types of situation, which trigger alarm bells those involved are often not even aware of,²¹ demonstrate that this age group is especially vulnerable to the control and monitoring behaviors typical of cyber dating violence,²² since, far

from considering them to be signs of an incipient problem, they interpret them as expressions of love and concern.²³

All this may become consolidated and normalized, and may even provoke an escalation of violence on the path towards adulthood.²⁴ Indeed, violence in adolescent couples is one of the strongest predictors of this same type of behavior in adulthood.^{25–27}

Furthermore, this type of behavior during adolescence often has negative consequences for those involved, including psychological, social, academic and physical problems^{28,29}. Research has shown that cyber dating violence is associated with increased depression and anxiety for victims, greater uncertainty regarding relationships, more antisocial behaviors, higher levels of hostility and even higher perceived stress levels than that caused by traditional aggressions.³⁰ Girls seem to feel differentially more upset when suffering this problem in their relationships.³¹ In the same line, a more recent study carried out with 604 Spanish adolescents, found positive correlations of cyber dating violence with depressive mood and cyber bullying victimization both in boys and girls, and with loneliness in girls.³²

The need for early prevention is therefore evident^{29,33–36} and there is a broad consensus regarding the fact that said prevention should begin before adulthood.^{37–42} In this sense, numerous prevention programs have been developed over recent decades^{43–46} which can basically be divided into two types: specific and universal. The former focus on the specific needs of the at-risk population. These prevention programs may be effective (either instead of or in addition to universal ones) for young people who have experienced violence in the family and community and who perpetrate or experience abuse in their early relationships.^{20,47,48} Among them, the Expect Respect Program⁴⁹ and the Youth Relationships Project²⁰ can be mentioned. On the other hand, universal programs, of which the Fourth R Skills for Youth Relationships²⁷ and the Safe Dates Project⁵⁵ are perhaps the most rigorous, usually aim to educate the general adolescent population about healthy relationships.^{27,50–54}

The prevention programs on dating violence are focused on working on aspects that have been identified as risk and protection factors within the “socio-ecological framework”.^{56,57} Thus, among the risk factors for victimization and perpetration, four types of factors can be distinguished, namely, individual factors, peer influences, family characteristics and environmental factors. So far, most programs have focused on addressing individual

factors and peer influences, as they have mainly been conducted in the school context and as part of the curriculum for students. Nevertheless, in recent years, programs have begun to address family and environmental factors too.³⁷

With regard to the specific contents they include, it seems clear that these are usually organized around three main and common content-blocks:⁵⁸ (1) developing socio-emotional competencies (eg self-esteem, empathy, emotional intelligence), (2) working on gender stereotypes or sexist beliefs and attitudes (eg rigidity in the definitions of masculinity and femininity, gender inequality), and (3) addressing attitudes towards partner violence (eg beliefs that justify violence, types of abuse or roles in dating abuse).

All these contents may also be maintained as part of the cyber-dating prevention violence programs, although in the latter the “online form” of violence should specifically be addressed with particular modules and concrete activities, given that it involves certain distinct features (for example, it can happen constantly, it can be more difficult to escape from, humiliating information can spread very easily, and it can engender stronger feelings of helplessness and discomfort).¹⁵ Moreover, it is much more difficult for young people to identify it, because its signs are more subtle and they often do not interpret them as violence “per se”.

To date, some reviews and meta-analyses on teen dating violence programs have already been conducted. Fellmeth, Heffernan, Nurse, Habibula, and Sethi⁵⁹ conducted a systematic review of educational skills-based interventions aimed to prevent the onset of and subsequent relationship violence among individuals between the ages of 12 and 25 years, and concluded that programs were effective in improving the knowledge of the participants. Another meta-analysis conducted by Edwards and Hinsz⁶⁰ (2014), which included eight teen dating violence prevention programs implemented from Grades 8 through 12, found that participants had lower scores on dating violence outcomes after the intervention compared with control participants. Finally, De la Rue et al³⁷ provided a quantitative synthesis of all the empirical evaluations of programs implemented in middle and high schools up to that point, and concluded that although programs were useful to improve knowledge, they did not affect behaviors to a significant extent.

Nevertheless, although reviews and meta-analyses of offline dating violence prevention programs exist, at the moment, there are no systematic reviews on cyber-dating violence prevention ones. Therefore, the present study

aims to fill this gap, by presenting a systematic review on the topic, focused on those programs that are directed to universal populations, and analyzing both their characteristics and the evidence presented of their effectiveness.

Materials and Methods

Type of Study

We planned to review articles that included cyber dating violence prevention programs, specifically those focused on the universal population.

Search Methods for Identifying Studies

This review follows the PRISMA statement for reporting systematic reviews and meta-analyses.⁶¹ The PRISMA Statement consists of a checklist of 27 elements and a four-phase flowchart. The objective of the PRISMA Statement is to help authors improve the reporting of systematic reviews and meta-analyses.⁶¹ We used PubMed, PsycInfo, Cochrane, Scopus and Web of Science to identify relevant articles. The search was conducted in September 2020.

We imposed no limitations linked to language, date, document type or publication status when searching for studies.

To retrieve as many potentially eligible studies as possible, we used a sensitive specific search strategy: (((cyber dating) OR (digital dating)) AND (dating violence)) AND (prevention).

We complemented the electronic search by scanning references from included studies and conducting a snowball search for studies quoting key references on cyber dating violence prevention programs.^{33,62,63}

Data Collection

To identify studies that met the eligibility criteria, the titles and abstracts of the retrieved articles were independently reviewed by three reviewers (J.J., N.G., I.R.). The full texts of all potentially eligible studies were then assessed by the same reviewers for inclusion in the review. Any disagreements about the eligibility of a particular study were resolved by discussion with a fourth reviewer (N.O.).

To be included, studies had to meet the following requirements: 1) they had to use a universal sample; 2) they had to include a prevention program; and 3) the prevention program must have as an explicit objective to reduce levels of cyber dating violence.

During our review we found many studies that included intervention programs, systematic reviews, meta-

analysis, empirical studies, test validation, clinical trials with no results or programs carried out in hospitals or with specific populations such as people who had suffered violence at home and which were not specifically targeted at the universal population.

We excluded all studies that did not specifically measure cyber dating violence prevention programs in universal populations.

Finally, we compiled a narrative synthesis of the findings reported by the studies included in the review.

Results

Figure 1 summarizes the PRISMA⁶¹ literature review procedure.

Out of 163 unique identified records, we retrieved 78 references after deduplication, of which 70 were considered irrelevant. Reasons for exclusion were: 1) intervention programs (3 references); 2) systematic reviews (15 references); 3) meta-analyses (1 reference); 4) empirical studies (45 references); 5) test validations (1 reference) and 6) clinical trials with no results (5 references).

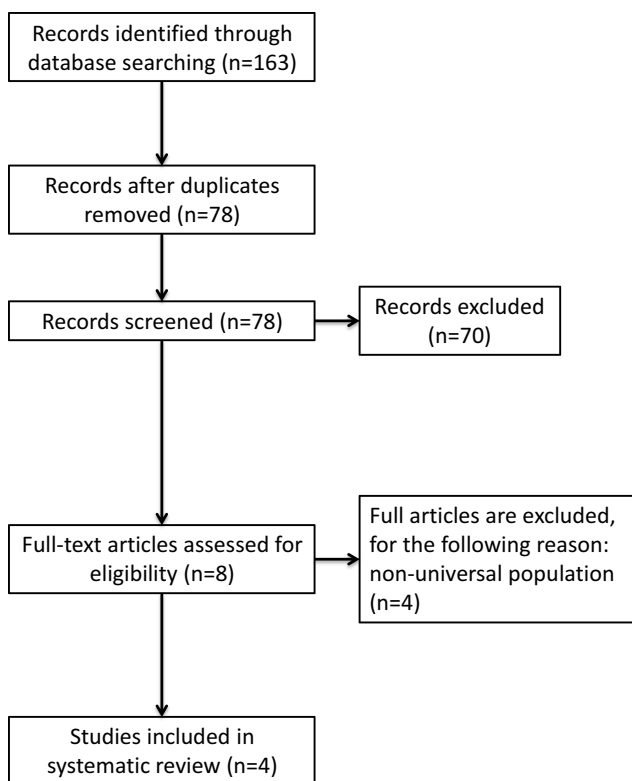

Figure 1 Flowchart of the review (n is the number of records/studies). **Note:** PRISMA figure adapted from Moher D, Liberati A, Tetzlaff J, Altman DG, The PRISMA Group. Preferred Reporting Items for Systematic Reviews and Meta-Analyses: The PRISMA Statement. *PLoS Med.* 2009;6(7):e1000097.⁶¹ Creative Commons.

We assessed eight full-text articles for eligibility. Of these, four were excluded because they were not conducted with a universal population. One of the excluded studies included a sample of adolescents with previous exposure to physical dating violence,⁶⁴ and another was excluded because the sample comprised patients in a pediatric emergency department or ambulatory care services.⁶⁵ Finally, two studies were excluded because they were about a dating abuse prevention program for teens exposed to domestic violence.^{66,67}

Overview of Included Studies

The four studies included presented the effectiveness results of three programs. The three prevention programs that matched the established search criteria (DARSI program, Date-e Adolescence program and a Brief Incremental Theory of Personality (ITP) intervention) are described below:

Developing Healthy and Egalitarian Adolescent Relationships - DARSI.⁶² This universal program is designed to prevent peer and teen dating violence among secondary school students (aged 12 to 16 years), by raising their awareness of the consequences of violence, enhancing their critical thinking regarding sexist attitudes and the myths of romantic love, strengthening their personal and social resources and favoring the development of healthy and more egalitarian relationships with peers and first romantic partners. The program comprised 12 one-hour sessions and was carried out by the researchers, although the authors also recommend training teachers to apply it in their classrooms and evaluate its effectiveness. The methodology combines role-playing, paper and pencil activities, case studies and guided discussion, using audiovisual materials, songs, drawings and stories about adolescents. As shown in Table 1, results about the efficacy of the program showed that the participating adolescents reported a decrease in frequency of peer aggressive behaviors (overt aggression, relational aggression, and cyber-aggression), in sexist attitudes (hostile and benevolent) and in beliefs in romantic myths, after the program implementation. Nevertheless, the lowest effect size was found for the cyber-aggression ($\eta^2 = 0.093$).

Date-e Adolescence.⁶³ A school-based, universal, multi-component prevention program for adolescents aged 11 to 19 years. This program is based on the Dynamic Developmental Systems Model,⁶⁸ which considers violence not as an individual process but as the product of interaction within different systems, where the developmental

Table 1 Results of the Efficacy Evaluations of Prevention Programs Designed to Prevent Cyber Dating Violence

Name of the Program	Sample n (Sex and Age)	Measures	Outcome	Assignment (Control Group)	Limitations
DARSI, Developing Healthy and Egalitarian Adolescent Relationships ⁶²	191 adolescents (88 boys, 103 girls), aged 12 to 17 years ($M=14.13$, $SD=1.05$) from two schools (one public and another semiprivate) in Spain.	-Scale of Cyber-aggressions among peers -CybAG-R ⁷³ -Ambivalent Sexism Inventory for adolescents (ISA-A, ⁷⁴ adaptation ⁷⁵). -Adaptation of the Romantic Love Myth Scale ⁷⁶ - School Aggression Scale ⁷⁷	Mean scores for variables indicating overt aggression (relational aggression, and cyber aggression), sexist attitudes and beliefs in romantic love were significantly lower among participants in the EG than among those in the CG. Effect-sizes (η^2) between 0.228 (for hostile sexism) to 0.093 (for cyber-aggression).	Quasi-experimental design with repeated measures (pretest and posttest). Convenience sampling. No randomized controlled trials (RCT).	No follow-up measurement (just pretest and following implementation). Small sample, small number of schools, which precludes the gender perspective being taken into consideration during the analysis of the program's effectiveness. Only self-reports were used. Observational techniques, instruments completed by teachers and in-depth interviews or focus-groups should also be used.
Dat-e Adolescence ⁶³	1764 adolescents (918 boys and, 846 girls) aged 11 to 19 years ($M=14.73$, $SD=1.34$) from seven schools in Spain, of a medium economic, social and cultural level and public or partially funded by the Regional Government.	- Dating Questionnaire. ⁷⁸ - Conflict Tactics Scale- CTS2. ⁷⁹ - Psychological Dating Abuse Scale. ⁵¹ - Cyber Dating Abuse survey. ⁸⁰ - An adapted version of the Myths of Romantic Love Scale. ⁸¹ - Network of Relationships Inventory: Behavioral Systems Version. ⁸² - Triangular Love Scale. ⁸³ - Cyberdating Q-A. ⁸⁴ - Emotional Quotient Inventory: Youth Version. ⁸⁵ - Rosenberg Self-Esteem Scale. ⁸⁶	No significant effects were found for physical, psychological and online aggression and victimization. No positive outcomes were found for couple quality. Significant changes were observed in beliefs towards violence, specifically regarding myths about romantic love (Cohen's d from -0.56 to -0.94); along with enhanced self-esteem ($d=-0.15$); and emotion regulation ($d=-0.19$).	RCT design with two waves (pre-test and post-test) and two groups (an experimental group and a control group).	No completely randomized trials: although the schools were randomly assigned to the control and experimental groups, it was the school staff who decided which classes would take part. Experimental mortality of approximately 25%. Intervention fidelity was assessed only by the implementing researcher.
Dat-e Adolescence ⁶⁹	1423 adolescents (734 boys and 689 girls), aged 11 to 19 years ($M=14.98$, $SD=1.39$), from seven schools in Spain, of a medium economic, social and cultural level	- Dating Questionnaire. ⁷⁸ -Conflict Tactics Scale- CTS2. ⁷⁹ - Adapted version of the sexual dating violence measure proposed by Foshee et al ⁸⁷ - European Bullying Intervention Project Questionnaire (EBIP-Q). ^{63,69,88}	The results revealed significant (small to medium) victimization and perpetration effects at follow-up: $d=0.21$ for severe physical dating victimization; $d=0.25$ for severe physical dating aggression; $d=0.24$ for sexual dating victimization; $d=0.38$ for sexual dating aggression; and $d=0.98$ for bullying victimization. No significant differences were found between groups in moderate physical dating aggression and victimization. ⁸⁰ The program did not modify bullying aggression.	RCT design with three waves (pre-test, post-test and follow-up at six months) and two groups (an experimental group and a control group).	No specific instrument was used to measure cyber dating violence. Self-report measures were used, which may be subject to social desirability bias. Results are not representative of very low-risk or very high-risk schools. No assessment of the differential effect of the program on boys and girls.

(Continued)

Table 1 (Continued).

Name of the Program	Sample n (Sex and Age)	Measures	Outcome	Assignment (Control Group)	Limitations
Brief Incremental Theory of Personality (ITP) from adolescent dating violence prevention program. ³³	123 adolescents (57 boys and 66 girls), aged 13 to 17 ($M=15.20$, $SD=0.99$), from four schools in the Basque Country (Spain). 11.1% low, 23.2% low-medium, 12.1% medium, 32.3% high-medium, and 21.2% high socioeconomic class.	- Ad hoc scale which covers different types of traditional (physical, psychological, and sexual) and online aggressions. The scale was based on previous validated scales for the assessment of different types of dating violence: the Conflict in Adolescent Dating Relationships Inventory (CADRI ⁸⁹), the Psychological Abuse in Partner Relationships Inventory, ⁹⁰ the Subtle and Overt Psychological Abuse of Women Scale – SOPAS ⁹¹ and the Cyber Dating Abuse Questionnaire. ¹¹	No effect of the ITP intervention on victimization. Perpetration of aggressive dating behaviors toward the dating partner (both traditional and cyber aggressions) decreased: from baseline to the 6-month follow-up, the effect sizes (Cohen's d) were 0.37 [-0.15, 0.89] and 0.27 [-0.25, 0.80], respectively; and from baseline to the 1-year follow-up, the effect sizes were 0.74 [0.18, 1.31] and 0.54 [-0.02, 1.10], respectively. No moderator effect of participants' sex on the effect of the intervention was found.	Double-blinded RCT with four waves (pretest, post-test, 6 month follow-up and 1-year follow-up) and two parallel groups (experimental vs control).	Small sample size. Only self-reports were used. Experimental mortality of 22.77% at the 6-month follow-up and 35.77% at the 1-year follow-up.

Abbreviations: EG, experimental group; CG, control group.

characteristics of both partners converge in a specific context or situation that would lead to conflict escalating into violence. Thus, the authors defend that dating violence is mainly mutual or reciprocal, and that peers play a relevant function, so it is necessary to take them into account.

The aims of the program are: (a) to raise awareness regarding concepts of love, myths about romantic love, and healthy behaviors in relationships; (b) to improve the recognition, expression, and regulation of emotions; (c) to enhance self-esteem; (d) to improve communication skills; (e) to raise awareness and promote coping and conflict-resolution strategies when aggression (both traditional and online forms of violence) occurs; and (f) to raise awareness of the influence of the peer group and bystanders in dating violence. The program is designed to reduce physical, psychological and online aggression and victimization.

It comprises seven one-hour long sessions carried out during school hours. The program is composed of a teacher sensitization module, a student curricular based module composed of seven lessons (1 hour per week), and a peer-led program. The program was implemented by the researchers (five sessions) and by previously trained peers (last two sessions). It combines classroom and web-based activities, the latter delivered over the program's online platform. Activities include role-playing, watching videos, debates, decision-

making games, displays and group dynamic exercises. The last activity is organized by the participating schools and covers the main contents and lessons learned during the intervention.

So far, two studies have explored the reliability of this program, as shown in Table 1. The first one⁶³ measured a wide range of variables related to dating violence (traditional and online) but did not include a follow-up measure. The second reliability study⁶⁹ included a reduced instrument-battery (in fact, no online dating violence instrument was administered) but added a follow-up measure. Results showed differences between post-test and follow-up results (lower aggression at follow-up), and authors emphasized the importance of measuring results at least 6 months after the interventions, because behavior modification requires time. It remains to be confirmed whether the program effectively reduces the levels of cyber-dating in the follow-up, since although the program includes the prevention of this type of violence as an objective, it has not been possible to evaluate whether there are changes in the follow-up in terms of cyber-dating violence.

With regard to generalizing the results, the studies have been carried out in high schools with a medium economic, social and cultural level, and the authors explain that the results are generalizable to a population bearing similar characteristics.⁶⁹

Brief Incremental Theory of Personality (ITP) adolescent dating violence prevention program.²⁵ Based on the experimental intervention by Yeager et al,^{70–72} this kind of intervention aims to replace entity theories of personality (ie, the belief that personal characteristics cannot be changed) with an incremental theory of personality (ie, the belief that people do have the potential to change). The intervention was administered by research assistants and comprises a single session lasting 50–60 minutes, divided into three main parts: (a) participants read neurological and behavioral studies that provide evidence that individuals have the potential to change. They are then asked to write two or three sentences explaining, in their own words, why scientific evidence shows that people have the potential to change; (b) participants read some normative quotes allegedly written by older children at their school who had previously read the same scientific information and endorsed the conclusions drawn; (c) participants are asked to describe a situation in which they felt withdrawn, rejected, or disappointed by another person at school. They are then asked whether they think any other classmates are feeling likewise due to the same situation, and are asked to write one to three paragraphs about what they would say to this person to help them understand that people and situations can be changed. Taking into account the previous positive results of ITP-based interventions in reducing externalizing problems in adolescents, this program aimed to prevent perpetration and victimization of dating aggressive behaviors (both online – cyberdating abuse – and traditional – face-to-face dating aggression) in adolescents.

The belief in the potential to change may modify how adolescents relate to their dating partners.³³ For example, if adolescents interpret the dating partners' behavior as a result of situational factors (for instance, having problems at school) her or his feelings of anger may be reduced, reducing perpetration of dating violence.

Table 1 summarizes the results of the validation studies of the three programs.

Discussion

Cyber dating violence is a highly prevalent phenomenon among adolescents and young people that needs to be addressed^{15,28} due to the significant adverse effects observed^{28,29} and the potential for these behaviors to continue into adult dating relationships.^{25,26} However, although the relevance of early prevention has been pointed out in different studies,^{33,36} prevention actions have mainly targeted “offline” rather than cyber dating violence. This same

trend is repeated in relation to meta-analytic and review studies. Indeed, to date, no studies of this kind have focused on this specific issue.

The present review constitutes a first attempt to describe and analyze the effectiveness of universal cyber dating violence prevention programs.

One of the main findings of this review was the paucity of cyber dating violence prevention programs targeted at young and adolescent couples. We found only three programs (four articles) that met our search criteria.

The three programs described give great prominence in their interventions to the cognitive and/or attitudinal component of behavior. DARSI and Date-e programs include also a skill-building component to promote the behavioral change, in line with the results of previous studies.⁴⁵

As for the theoretical basis of the program, the Date-e and the Brief ITP program do include a theoretical explanation on which they base their intervention, but DARSI does not. It is important that the programs include a theoretical justification of their proposal, since it gives more meaning to the content of the program. Thus, based on the Dynamic Developmental Systems Model, the authors of the Date-e program suggest the need to undertake future analyses on the possible mediating effects of the variables they have studied on dating violence. Similarly, the Brief ITP program defends theoretically that the adolescents' belief in the potential to change may modify how they relate to their dating partner.

All three had been validated and the results regarding their efficacy clearly outlined in respected scientific journals. Two of the programs (Date-e Adolescence and the Brief ITP program) used RCT designs. The limitations found during the validation process include small or barely representative sample sizes, exclusive use of self-reports in the evaluation, sample mortality, lack of follow-up evaluation and no differentiation by sex.

Regarding effectiveness, as with programs focusing exclusively on offline violence, it appears that the goal of changing beliefs and attitudes was achieved in the case of cyber violence prevention programs. Thus, it is important for cyber violence prevention programs to include activities that aim to modify potentially dangerous attitudes, such as those related to the myths of romantic love, sexist attitudes, self-esteem and cognitions linked to beliefs about the possibility of changing people and situations, etc.

The programs' effectiveness in changing violent cyber dating behaviors is less clear. One of the key aspects to be

taken into account is the importance of carrying out evaluations beyond the post-test moment (ie, follow-up evaluations). As observed in the e-Date Adolescence program, although no significant results were found for aggressive behaviors at post-test, this changed when a design with three waves was used. The same effect is also evident in the results reported by Fernandez-Gonzalez et al (2020).³³

De la Rue Joshua, Polanin, Espelage & Pigott (2014)⁴⁴ stress the importance of time lapses in behavior modification: changes in behaviors require time and the development of socio-emotional skills for coping with conflicts within the couple. It may be that students simply do not have the opportunity to put what they have learned into practice in the short time that elapses between the completion of the programs and the post-test evaluation. Thus, follow-up measurements are clearly advisable.

Moreover, with the aim of encouraging changes in behavior, programs should include skill-building components such as emotion regulation, communication skills, and coping and conflict-resolution strategies.⁶⁹

Nevertheless, although the effectiveness of these programs is evident, it should be noted that none of them seem to address cyber-violence in a specific way and with concrete activities. In this sense, it should be advisable that these programs not only help participants recognizing the signs and expressions of this type of violence, but also provide ways to protect against it, for example, by teaching adolescents and young people how to navigate safely, raising their awareness about the importance of not sharing certain private information on the Internet, and/or explaining how to select and use passwords appropriately, etc.⁹² In fact, these are common to other programs that prevent online violence, even if not in the context of dating.⁹³

In terms of program duration, the three programs analyzed varied in length from one (Brief ITP program), to seven (Dat-e Adolescence) to 12 sessions (DARSI). Although the single-session program was successful, it is clearly much more limited in terms of the objectives it sets. The duration of the other two programs is very similar to that of dating violence prevention programs, and is also in line with what some authors claim is the format that delivers the best results (10–12 sessions).⁹⁴

As for the implementation of the programs, the three programs were implemented by researchers, but it would be advisable to train school-staff to apply the programs in their classrooms and to test the program's efficacy under more natural implementation conditions.

The advantages of universal prevention programs are important, such as being able to reach a greater number of subjects and focus on the problem before it appears, but it is not without drawbacks. When considering universal programs to prevent violent behavior, the “floor effect” may occur, because this effect could attenuate the detection of intervention effects of universal programs, as reported in other studies about school violence.⁹⁵ The low baseline exposure to dating violence in the scholar population makes it more difficult to find differences related to the implementation of the program. Future studies should also test the program efficacy on participants with higher levels of exposure to violence, or high-risk populations.⁶³ Moreover, we might think that the earlier the intervention, the better we can prevent the problem behavior, but analyzing the effectiveness of interventions on early adolescents have to deal with the difficulty that a number of adolescents have not begun dating relationships, which is an obstacle to obtain large samples.³³

In sum, in light of the above, future studies should aim to recruit larger validation samples, analyze sex-related differences in results and try to replicate the findings in samples from other countries. Moreover, in order to improve the evaluation of the programs' effectiveness, self-reports should be complemented by observational measures, qualitative information and/or instruments completed by teachers.⁶² The specific effects of the programs at a behavioral level should also be closely examined, as they are often focused on changes in attitudes or on topic-relevant knowledge gain,⁹⁶ but this alone is not sufficient to guarantee changes in actual behavior.⁹⁷ Finally, given the importance and scope of the phenomenon, it is vital to develop a greater number of specific prevention programs, or to validate some existing proposals⁹⁸ which, despite being of great interest, have not yet been evaluated.

One of the strengths of this revision is the use of the PRISMA method, which provides good scientific evidence and has been supported by numerous high impact biomedical journals and prestigious institutions (eg Cochrane Collaboration).

With respect to limitations of this review is the small number of studies included, which limits the applicability and generalizability of the review's conclusions. Given this limitation, we were unable to compare and draw conclusions about specific components of the programs, such as age sub-groups possible differential effectiveness or the

efficacy of the concrete contents included in each intervention.

Nevertheless, this work has shown that there is a scarcity of studies on cyber-dating violence prevention programs in universal populations and opens a field of research for the creation of new programs.

Acknowledgments

The Research Project was sponsored by the University of the Basque Country, UPV/EHU, with grant number PPGA20/09.

Psychology Research and Behavior Management

Dovepress

Publish your work in this journal

Psychology Research and Behavior Management is an international, peer-reviewed, open access journal focusing on the science of psychology and its application in behavior management to develop improved outcomes in the clinical, educational, sports and business arenas. Specific topics covered in the journal include: Neuroscience, memory and decision making; Behavior modification and management; Clinical

applications; Business and sports performance management; Social and developmental studies; Animal studies. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/psychology-research-and-behavior-management-journal>
